On RX, the incoming signal from the antenna should go thru a bandpass filter, get some pre-amplification, get mixed with the L.O., and the filter should pass the difference (6 meter signal) with possibly some small signal amplification then on to the 6M RX.
Transverters are fun, simple and relatively inexpensive (compared to having to buy another all mode VHF rig). Give it a try !

I think what you are referring to is a PIN diode. This part is effective for switching rf paths on and
off. They have a very slow switching speed >100khz and will not rectify r.f. frequencies. I have
used generic 2.5 amp power diodes for the same purpose in several projects. They work fine as
long as you don't need a high degree of I/O isolation.

> (resistor/cap values to try, a new topology... anything)
> thanks... bern
>

Bern:
Build your voltage amplifier as you outlined, but DC couple an emitter follower to the collector of the gain stage. Drive the modulated stage from the emitter follower. This will give you the current drive you'll need to supply the modulated Vcc. The CE gain stage won't quite get down to 0 volts on the negative peaks, and the emitter follower will add another 0.7 volts to the minimum swing, but this should still be plenty of swing to modulate the stage nicely.

Good luck,
Joe

1694. A cheap microwave transceiver?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-01 00:00:00 UTC
From: jmhill@duck.WPI.EDU
Message-ID: <3o3rn3$87t@bigboote.WPI.EDU>
Source record: 113245

Hello all;
I am a member of the ham radio club at Worcester Polytechnic Institute
in Massachusetts. Sorry, I am not offering a transceiver, actually
I am looking for information regarding a transceiver.

Recently I heard of a fellow who was building low power
microwave transceivers by using parts from old radar detectors.
A local ham radio clubs had a speaker who presented one of the
transceivers he had build. I'm not sure but I believe that the
transceiver operated in the 10 GHz band, with extremely low power.

The story goes that, for a few bucks you buy an old radar detecter, then
gut the detector for parts to make your transceiver. I guess all radar
detectors incorporate a gunn-plexer. With some kind of modification the
gunn-plexer will transmit, as well as down convert received signals.
Beleive it or not, the fellow who presented his transceiver used a
Ra*io Sh*ck portable radio as the IF demodulator.

We are looking for a simple, low cost project so that a number of people
can each build their own. The idea of using parts from a radar detecter
appears to have sparked our imagination. At this point, as far as microwaves
are concerned, most of our club members are ``newbies'' but think that such
a project would be a fun way to get our ``feet wet'', so to speak. Who knows,
this could lead us to bigger and better things....

So in summary, I'd like to ask if there is anyone out there who has
constructed such a transceiver from radar detector parts? Does anyone have
information that you think might be useful?

Jonathan Hill/N1QOL

WPI Ham Radio Club, W1YK since 1913.

Hello Joe, I just picked up one myself. I am told they will take like -17 to -21 volts or so but stick to -19. You will blow a transistor if you got t0 -23. I put a meter on the phase pin and a spectrum analyzer on the output. When it is not locked the voltage was -4 volts or so. When locked it went to -13 or so. Also when it is locked it will stop sweeping. Mine outputs around 10.7 ghz. I have not got as far as returning yet but I was talking to WB1FKF this weekend. I will check that call again I am taking it from memory. If it is wrong I will send you another msg. He is really the guy to talk to he has successfully retuned them to 10 ghz. I have his number home and I am at work. They start off drawing like 700ma I measured but I am told when the oven warms up they drop to 500ma or so. I asked him the same question about schematics and he has none. But he says you can figure it out it's not that bad. Keep me posted if you find anything new out please. 73's Viny N1VC

Toko make a range of helical filters that might help. The 271MT1008
has a centre frequency of 145 MHz and a BW of 2 MHz. The I/O impedance
is 50 ohms. They cost just over 5 pounds here in the UK.

Pat Hawker, in his Technical Topics column in RadCom, discusses parametric *mixers* in the current issue. I remember him saying many years ago, when discussing the same thing, that parametric mixers and amplifiers can handle several signals of a volt or more if they are pumped at a suitable high level (several volts). Quite a lot of work was published on parametric amps when I was at college, in 1963 or thereabouts. I remember one design that used the collector-base junction capacitance (I think) of an HF transistor as the non-linear element of a parametric mixer, combined with the standard RF amplification of the transistor. I tried building a similar circuit, but couldn't get it to work.

Hello Ron,
It does not sound like you are afraid to open one of those puppies
up, so you are in luck. Find out the part number of the power amplifier, it
will be the module nearest the top of the radio. I can tell you from that
what band it is in, and then will tell you the particulars of how to move
it into the amateur band.
If the radio is 16 or more channels, or has an a/b zone switch on top,
(also should be marked on top escutcheon as MX300-S, it will make a fine
ham Transceiver... will tell you more as you ask

Jonathan,

The gunnplexers you have in mind are a nice thing, (I built one about 12
years ago), but there are a few catches, you want to be aware of:

This wide band FM communication was done many years ago, when
the components cost hundreds of $, and allowed direct sight
communication over 100+ miles, between hill tops. Then they were the only
way to be QRV on microwaves.

Now days everyone has turned to low noise narrow band systems,
which offer a vastly enhanced range, and the gunnplexers are not
really used anymore with the exception of fast data links.

So If you want to build a few of these TRX in a group, you are fine,
but do not expect to have many QSO-partners in the rest of the world.
Also, if you want more than a few miles range, you need good antennas, which
envolve quite a bit of metal work, and you also need waveguide and flanges.
BTW, some gunnplexers (side-by-side units) cannot be connected to a proper
antenna.

I went through this same debate a little while ago. With the cost of hardware and software tools totaling $2k or better for a medocre system, I stopped and started looking for other (less costly and maybe even easier to use) options. Ed Nisley from CCS mag (and BBS) did a series on IBM type PCs. You can get both hardware and software FAR cheaper than 8051 stuff (unless you have good sources - and you probably wouldnt be asking these questions). I have seen dirt cheap 8086 and better hardware at hamfests and computer shows. Quick or turbo C cost $100. buy / build an EPROM programmer or just load compiled code from a floppy (they cost $15 these days used or surplus). You can buy / build interface boards to plug into 8bit slots or build a "parallel controlled" interface.

I know its overkill on hardware, but its an example of "economy of scale". They build so much of this stuff that its easy to come by. I suggest that if the goal is to control something - go PC (80x86). If the goal is to use an 8051/8032 - go for it! (good luck).

My old homebrew QRP transmitter blew its final amp. I can't find my old schematics and notes. The blown transistor is a Motorola HEP S3001. I'm sure this is obsolete. Can someone help me find a replacement device number or send me the vital statistics on the old S3001.

The .5 and 9.5 is definitely the cleaner mix.

The other one will have incurable problems with harmonics of the
input signals falling into the output band.

I am looking for help understanding how i may use a power supply i just came upon. It is an "electronic measurements" company supply. it has terminals in front marked load witha resistor symbol above it. there are many terminals in the back. when turned on there is no output. I believe you must proved the unit with input in the form of voltages and resistances in order to obtain output. here is my problem. how do i do this. any help will be appreciated.

>harmonics or noise using one or the other?

Just be sure that your filter manages to get rid of the signals you don't want. If you use 0.5MHz and 9.5MHz you get 10MHz and 9MHz plus harmonics and the two input signals. The filter has to be able to isolate the 10MHz signal from the the other signals. The closer the unwanted signals are to the 10MHz signal, the more selevtive the filter has to be.

(There are also other considerations to take.)

Hello everyone,

There was mention here on the Internet the other day of a T1 rf
modem being built or designed. Like a dolt I did not save the file and
am not able to locate it at this time either. If anyone has information
on the T1 modem could you please forward it to me? Thanks.

1714. Announce: ACS (Al's Circuit Simulator) version 0.17 available

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-02 00:00:00 UTC
From: al@atd.rochester.ny.us
Message-ID: <1995May2.153107.13597@atd.rochester.ny.us>
Source record: 113126
Cross-posted to: comp.lsi,comp.lsi.cad,sci.electronics.cad,sci.electronics,rec.radio.amateur.homebrew

A new release of ACS has been posted to alt.sources and is available
by ftp from cs.rit.edu in pub/acs.

ACS is a general purpose circuit simulator. It performs nonlinear
dc and transient analyses, fourier analysis, and ac analysis
linearized at an operating point. It is fully interactive and
command driven. It can also be run in batch mode or as a server.
The output is produced as it simulates. Spice compatible models
for the MOSFET (level 1 and 2) and diode are included in this
release.

This version (0.17) is a transitional release in C++. There are
a few bug fixes.

Since it is fully interactive, it is possible to make changes and
re-simulate quickly. The interactive design makes it well suited
to the typical iterative design process used it optimizing a circuit
design. It is also well suited to undergraduate teaching where
Spice in batch mode can be quite intimidating. This version, while
still officially in beta test, should be stable enough for basic
undergraduate teaching and courses in MOS design, but not for
bipolar design.

In batch mode it is mostly Spice compatible, so it is often possible
to use the same file for both ACS and Spice.

The analog simulation is based on traditional nodal analysis with
iteration by Newton's method and LU decomposition. An event queue
and incremental matrix update speed up the solution for large
circuits.

It also has digital devices for mixed signal simulation. The
digital devices may be implemented as either analog subcircuits or
as true digital models. The simulator will automatically determine
which to use. Networks of digital devices are simulated as digital,
with no conversions to analog between gates. This results in
digital circuits being simulated faster than on a typical analog
simulator, even with behavioral models. The digital mode is
experimental and needs work. There will be substantial improvements
in future releases.

ACS also has a simple behavioral modeling language that allows
simple behavioral descriptions of most components including capacitors
and inductors. Unfortunately, it is not well documented.

ACS uses an object oriented approach to modeling. Complex models like MOSFETS are made of simpler ones like resistors, capacitors, diodes, and any other models that may already exist. The model designer does not need to worry about details like convergence checking, bypass checking, integration, or how the new device plugs into the solution matrix because these are already taken care of by the basic models. This results in a dramatic improvement in the time it takes a researcher or model designer to install a new model, compared to Spice.

The source and documentation can be obtained by anonymous ftp from ee.rochester.edu or cs.rit.edu in /pub/acs. It can also be obtained by dial-up (USA) 716-272-1645 in /pub/acs. It may be distributed under the terms of the GNU general public license. The dial-up also has some test circuits, pre-compiled executables for Linux, Sun4, MSDOS and possibly others, and documentation in latex, dvi and postscript.

If you are tired of Spice and want a second opinion, you want to play with the circuit and want a simulator that is interactive, or you want to study the source code and want something easier to follow than Spice, try ACS.

ACS is an ongoing research project. It is being released in a preliminary phase in hopes that it will be useful and that others will use it as a thrust or base for their research. I also hope for some comments that may help me direct my research.

Albert Davis, 136 Doncaster Rd., Rochester, NY 14623.

1715. Re: Small Transmitting Loops

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-02 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <3o6v2j$c3u@newsbf02.news.aol.com>
Source record: 113127

The primary problems are insuring a low resistance path for the high circulating currents. The use of ANY dielectric in the capacitor other than air or vacuum is a no no. Never use a braided conductor, try to use a smooth large diameter round conductor. Don't use pressure connections in the loop, like the wipers or bearings in an air variable. Use a welded butterfly type or flapper plate tuning cap.

If you do all this you will approach a full size dipole with a small loop. One word of caution, people are saying to use TFE piston caps in the loop, but TFE is as lossy as Polyethelyne for RF. I removed some TFE piston caps from a medical loop and installed flapper caps with air insulation and direct connections. The eff went up dramatically (several times).

1717. My List of Mail Order Electronics Companies

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-02 00:00:00 UTC
From: jfw@proteon.com
Message-ID: <D7yF6C.9py@proteon.com>
Source record: 113258
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.info

It has been a while since I posted this, and some parts may be seriously out of date. I hope to be able to find time to verify more of this list soon and post any needed corrections. Note that updated copies are available via WWW and FTP from my home system, funhouse.com.

[$Revision: 2.18 $; last updated May 2, 1995]
[Author: John Woods, WB7EEL, jfw@jfwhome.funhouse.com]

Here is my list of companies which will sell electronic components in small quantities. Many of these places I have bought from, several I haven't. Being a ham radio operator, I am most interested in RF components, and in particular, air variable capacitors, which tend to be scarce (and tend to be used or surplus even if I've otherwise labelled the seller as "NEW").

Categories are:
NEW COMPONENTS Distributors and sellers of new components, or "new and some used" in a couple of cases.
SURPLUS ELECTRONICS Usually overstocks, occasionally used equipment. Ideal for stocking the junkbox, usually have dependable stock lines of resistors, capacitors, and some semiconductors, but won't have those LCD modules forever... An invaluable resource, don't shy away from them.
SPECIALTY COMPONENTS In particular, crystals and toroidal cores.
KITS Ham radio kits, random electronic kits, whatever they have.
LITTLE GUYS Separated out because of some twisted sentimentality, I suppose. Intended to honor one or two ham spare-bedroom operations. Note that sending $1 along with catalog requests is a big help for these folks.
PUBLICATIONS A small selection of publications dealing with electronics, especially RF electronics.
QRP CLUB PUBLICATIONS Clubs for low-power amateur radio enthusiasts; frequently have publications with quite a bit of technical content (which is why I'm a member of QRP clubs headquartered thousands of miles from where I live :-). Note, this is generally practical technical content (how to build it) rather than theoretical technical content (why it works), but definitely more than Contester's Quarterly.

Note on shipping costs: I don't always update these frequently enough, and they're generally for continental US unless otherwise mentioned.

NEW COMPONENTS:

Digi-Key
701 Brooks Ave. South

P.O.Box 677
Thief River Falls, MN 56701-0677
+1-800-DIGI-KEY (344-4539)
+1-218-681-3380 (FAX)
No minimum, $5 handling under $25, free and very complete catalog, very nice indeed. Prices aren't always the best, but rarely excessive. Weak on RF specialty parts (though they now have the ever-popular NE602AN), but they do have blue LEDs.

Mouser Electronics Mouser Electronics Mouser Electronics
11433 Woodside Ave. 2401 Highway 287 North 12 Emery Ave.
Santee CA 92071 Mansfield TX 76063 Randolf NJ 07869
Mouser Electronics
370 Tomkins Court
Gilroy CA 95020
Catalog Subscriptions: (800) 992-9943 (Continental US only)
Sales & Service: (800) 34-MOUSER (800-346-6873) (US, Puerto R., Canada)
Very complete catalog of brand-new components (though no air variables). Usually quick service, $20 "minimum" ($5 charge under $20). When ordering, you may want to be sure to ask about availability and shipping locations; they have several warehouses, and frequently orders will get sent from several warehouses (which drives up the shipping costs). Export orders have a $100 minimum, except for Canada and Mexico.

Ocean State Electronics
P.O. Box 1458
Westerly RI 02891
+1-800-866-6626 (orders)
+1-401-596-3080
+1-401-596-3590 (FAX)
Minimum $5, S&H $4, $2 for catalog. Wide array of RF parts, especially air variables and B&W coils. Reportedly getting a bit slow filling orders.

Radiokit (store is located at:)
P.O.Box 973 169 Jeremy Hill Rd.
Pelham NH 03076 Pelham NH 03076
+1-603-635-2235
+1-603-635-2943 (FAX)
No minimum ($3 service charge if under $20), many kits, lots of J. W. Miller chokes & coils, B&W coils, RF switches, Millen variable capacitors, lots of parts in general. As of 24-Feb-94, they are again STILL out of catalogs, and just barely might have one by Dayton this year. They do accept mail orders, but you'll have to call for prices and availability. A classified ad in 3/94 QST says "Call/SASE", I guess they may have fliers.

Circuit Specialists Inc
P. O. Box 3047
Scottsdale AZ 85271-3047
+1-800-528-1417
No minimum with check or money order, $15 otherwise. $3 S&H.
New electronics, good RF assortment, increasing infestation of computers.

Active Electronics
11 Cummings Park 237 Hymus Blvd
Woburn MA 01801 Pointe Claire, Quebec, H9R 5C7
+1-800-677-8899 (Main number for US and Canada)
+1-514-630-7410 (International)
+1-514-697-8112 (FAX)
$25 minimum, $5 S&H UPS, catalog has a "$10 Suggested retail price" but they sent mine for free. They have 7(?) stores in the US (Chicago IL; Baltimore MD; Woburn MA; Detroit MI; Mt. Laurel NJ; Long Island NY; Seattle WA) and 10 stores in Canada (Quebec City; Montreal (2); Ottawa; Mississuaga; Winnipeg; Calgary; Toronto; Edmonton; Vancouver BC). Each store has its own 800 number and FAX number, call the main number(s). International orders are to be mailed to the Canadian address, but they want payment in US funds! Lots of stuff, oriented more toward supplying last-minute requirements of companies than hobbyists, but perfectly happy to take your money in small doses (stores have no minimum order). The $25 minimum for certain items is no longer explicit, but they note that some items will "ship in factory minimum package quantities", which might be worse.

Maplin Electronics Ltd.,
P.O. Box 3,
Rayleigh,
Essex,
SS6 8LR
U.K.
Phone numbers: your international code +44 702 554161 for sales
+44 702 553935 Fax
+44 702 556001 Tech enquiries(2-4pmGMT)
"Over here [in the United Kingdom] the main hobbyist electronics supplier is Maplin Electronics who stock a wide variety of equipment. They have a catalogue which can be shipped for 10.65 pounds sterling by air or 5.50 pounds sterling by surface mail. They accept Mastercard, American Express and International Reply Coupons. They have at least one type of air-filled variable capacitor!" (Thanks to Kev White at Cambridge University).

Newark Electronics
Send catalog requests to:
Newark Electronics
ATTENTION CATALOG DEPARTMENT
4801 N. Ravenswood Ave.
Chicago IL 60640-4496
+1-312-784-5100
They don't have a single mail address or phone; instead, one is supposed to call the closest of three pages worth of branch offices. I don't feel like typing in the entire list (it's copyrighted, anyway :-), so send email for your "local" distributor, or call their administrative offices at the number above. They have a $25 minimum order; they are a Real Distributor, but accept small orders (over the minimum, of course). Their catalog currently 1488 pages; they are very complete (except, of course, for my favorite scarce item, the air-variable capacitor). Note that the catalog prices tend not to match reality all that often, so order by phone rather than by mail; prices tend to be higher than other places, but they have a lot

of things that are hard to find from other outlets. Also note that they have six Canadian offices, and one UK office, and will take international orders at 500 N. Pulaski St., Chicago IL 60624-1019, +1-312-784-5100 (FAX +1-312-638-7652, TLX 6718690 NEWARK U).

Arrow Electronics, Inc. Catalog requests to:
Catalog Division Catalog Division
1860 Smithtown Ave. 25 Hub Drive
Ronkonkoma NY 11779 Melville NY 11747-9828
+1-800-93-ARROW
Minimum $25; they no longer have a catalog. They are a Real Distributor, but also didn't mind my placing a personal order (a couple of years ago).

MCM Electronics
650 Congress Park Drive
Centerville OH 45459-4072
+1-800-543-4330
+1-800-824-TECH (product questions)
+1-513-434-6959 (FAX)
Minimum $20 ($25 for charge cards, and they don't take personal checks), handling $1.95 + shipping. Oriented toward repair technicians, really heavy on VCR parts and somewhat overpriced doodads, lots of useful stuff not easily found elsewhere.

Fordham Radio Supply
260 Motor Parkway
Hauppauge NY 11788-5134
+1-800-695-4848
Tools for technicians. One or two items are not outrageously overpriced.

Jameco
1355 Shoreway Road
Belmost CA 94002
+1-800-831-4242
+1-800-237-6948 (FAX)
+1-415-592-8097
No longer have a minimum order, reasonable selection of parts again (in addition to computer components).

JDR Microdevices Just moved!
1850 South 10th Street
San Jose CA 95122-4108
Orders: +1-800-538-5000
+1-408-494-1400
FAX: +1-800-538-5005
+1-408-494-1420
Cust. Service: +1-800-538-5001
Tech Support: +1-800-538-5002
BBS: +1-408-494-1430
No minimum, $5+ shipping. Mostly computers now, but they haven't yet decided to abandon components; indeed, they recently dropped their minimum order requirement entirely.

Johnson Shop Products
P.O.Box 160113
Cupertino CA 95016
+1-408-257-8614
+1-408-253-6288 (FAX)
Catalog $1. No minimum. Shipping charge is based on UPS; very small orders that can be sensibly shipped in a first-class letter, include money for first-class postage. New and some used electronic parts.

DC Electronics
P. O. Box 3203
Scottsdale AZ 85271-3203
+1-800-423-0070 (orders)
+1-602-945-7736 (stock/price checks)
+1-602-994-1707 (FAX)
$15 minimum charge order, no minimum for checks, $3 min. shipping&handling.
Wide array of ICs, good assortment of electronic components.

Communications Specialists, Inc.
426 West Taft Ave.
Orange CA 92665-4296
+1-800-854-0547
+1-714-998-3021
+1-714-974-3420 (FAX)
Surface mount chip component prototyping kits, $49.95.
Call for free detailed brochure.

Kelvin Electronics
7 Fairchild Ave.
Plainview NY 11803
+1-800-645-9212
+1-516-349-7620
+1-516-349-7830 (FAX)
Minimum order $20; S&H 5% of order ($5 minimum, extra for large stuff, overnight, export (like to Hawaii :-), and etchant; based on UPS charges).
Lots of electronic parts & tools, some robotics supplies, model rockets.

H & R Company (Herbach and Rademan)
18 Canal Street, P.O.Box 122
Bristol PA 19007-0122
+1-800-848-8001 (Orders)
+1-215-788-5583
+1-215-788-9577 (FAX)
Minimum order $25 ($5 processing charge under $25), shipping $4.75 under $30;
Most items are new overstocks, much regularly stocked stuff as well. Tools, electrical supplies, motors, mechanical components, robotic components.

John Birkitt
1, The Strait, Lincoln
+44 522 520767
Lots of stuff for the practical enthusiast. Many bargains to be had if you've the patience to sort through the extensive heaps of assorted electronic miscellany. Good stocks of new components, tools and books,

masses of RF gear and very competetive prices.
Two shops side by side cater for the "consumer" type goods and the
"electronics" type. Does mail order, takes visa/access etc. Mail order
list contains lots of unusual goodies that you'll possibly never see on
offer anywhere else. (thanks to Dave Walster @ lincoln.gpsemi.com)

N R Bardwell
Abbeydale Road, Sheffield
+44 742 552886
Possibly the busiest electronics emporium I've ever visited. Specialises in
radio gear and alarm equipment but many of the obligatory bags of "unmarked,
untested" goodies makes Bardwell's *the* place to go. Friendly, efficient
and knowledgeable staff. Cheap. Very cheap. Thriving mail order business
with some good bargains in IC's and discrete's. Write/phone for a price
list. (thanks to Dave Walster @ lincoln.gpsemi.com)

International Components Corporation
1803 NW Lincoln Way
Toledo OR 97391-1014
+1-800-325-0101 (US & Canada)
+1-503-336-4400 (FAX)
Cabinets&Enclosures; Capacitors; Diodes; ICs; Potentiometers; Resistors;
Sockets; Transistors; Books. No minimum order, $2 handling under $25.

SURPLUS ELECTRONICS:

All Electronics Corp.
P. O. Box 567
Van Nuys CA 91408-0567
+1-800-826-5432
+1-818-904-0524
+1-828-781-2653 (FAX)
NO minimum, $5.00 S&H. New and surplus electronics.

Alltronics
2300 Zanker Road
San Jose CA 95131
+1-408-943-9773
+1-408-943-9776 FAX
Surplus electronics. $12 minimum, shipping per UPS.

American Science and Surplus (formerly JerryCo)
3605 Howard Street
Skokie IL 60076
+1-708-982-0870
+1-800-934-0722 FAX
Surplus. *The* surplus place. Lots and lots of surplus. WWII gun cameras,
velcro, laser disk chassis, 6 volt VW wipers motors, LEDs, rubber brains,
you name it, they've had it. Catalogs are a really good time.
$12.50 minimum order (which includes the $4 shipping charge).

BCD Electro ### Out of the mail order business!
P. O. Box 450207
Garland TX 75045-0207
+1-214-343-1770
According to Barrie Britton (24 Feb 94), BCD has gone out of the mail order business.

Fair Radio Sales
P. O. Box 1105
1016 E Eureka St.
Lima OH 45802
+1-419-227-6573
Surplus electronics. Heavy on parts for old Collins gear.

Hosfelt Electronics
2700 Sunset Blvd.
Steubenville OH 43952
+1-800-524-6464
+1-614-264-5414 (FAX)
No minimum, $3.75 S&H. Surplus electronics.

$10 minimum. Surplus electronics.
"Also known to stock many components, but this is not discussed in the catalog. Local store, a cleveland institution, is called Electronic Surplus, Inc., and has been there since '48. Third generation now runs it." -- wb8foz
7/13/94: Dave Lesher (wb8foz) updates their hours as M,W,F 0900-1900; T,R 0900-1600; S 0900-1500; but wasn't sure if that was the store hours or the order line hours (but likely both).

Surplus Sales of Nebraska
1502 Jones Street
Omaha, Nebraska 68102
+1-402-346-4750
+1-402-346-2939 (FAX)
New and surplus radio electronics. Wide selection: air variables.
Catalog $3 (free with order, refundable with $25 catalog purchase).

Tucker Surplus Store
1717 Reserve St.
Garland TX 75042
+1-800-527-4642 extension 135
Surplus electronic gear; oscilloscopes and signal generators from the days
when dinosaurs with vacuum tubes roamed the earth (some solid state gear, but
all well used). Prices seem relatively high, and you'll be shocked to learn
how much it costs to ship a 75 pound oscilloscope by motor freight...
[Steve Brown, N8HFI:
In defense of Tucker, the have a broad selection, repair facilities, and
they certify the used equipment to meet the original specification and
warranty it for 90 days. Not every source does this:]

Davilyn Corp.
13406 Saticoy St.
North Hollywood, CA 91605-3475
+1-800-235-6222 (Ex. CA)
+1-818-787-3334 (CA)
+1-818-787-4732 (FAX)
Surplus electronic gear.
[has much better prices [than Tucker], but sells used equipment as-is. -N8HFI]

SPECIALTY COMPONENTS:

JAN Crystals
2341 Crystal Drive
P.O. Box 06017
Fort Myers FL 33906-6017
+1-800-JAN-XTAL (Monday through Thursday)
+1-813-936-3750 (FAX)
+1-813-936-2397 (plant)
They make crystals. Minimum order is $10, which might be one crystal, or
might be two.

Crystek Corporation
2351/2371 Crystal Drive
P.O. Box 06135
Fort Myers FL 33906-6135
+1-800-237-3061 (M-F) (US and Canada but not Alaska and Hawaii)
+1-813-936-2109
+1-813-939-4226 (FAX)
They make crystals too. They were the cheapest last time I ordered, but
I don't have an up-to-date price list. It took about 4 weeks, and they
had said it would take 6.

ICM (International Crystal Manufacturing Co., Inc.)
701 W. Sheridan
PO Box 26330
Oklahoma City OK 73126-0330
+1-800-426-9825
More crystals. They were more expensive, but they have lots of pre-made crystals for various rigs, so they would probably be faster.

Amidon Associates
3122 Alpine Way
Santa Ana, Calif. 92074
+1-714-850-4660
Toroid cores and related things. Very fast service. Now takes MC/Visa and phone orders. I *think* this is their current address, they seem to move a lot.

Palomar Engineers
Box 462222
Escondido CA 92046

Sorry Dave, but low_profile still makes me think of small, short radios.
Not low impact operating. There is also the '/', I'm not certain it's
allowed in group names, at least I couldn't find any current use of it.
I still think that qrp or qrp_something_else would work better. Let's see

rec.radio.amateur.qrp I think this has been voted down
before, but I don't understand why
.low_profile I don't think it tells the 'story'
.qrp_low_profile As above
.qrp_hidden Just thought of this one
don't know how good it would
really be, but it could cover
qrp, fox-hunts and 'low_profile'

> Chris N7RME

I'd think it would be much easier to just run the rigs off the batteries
all the time, with a charger capable of keeping up with the average load on
the batts. This way, the charger doesn't need to hold up the entire output
of the drain of the radio while in transmit, but always keeps the batteries
topped off. Of course, you should provide for a way to monitor whether the
charger is actually on.... A local repeater here has a similar setup, and
the charger failed... It was about 2 weeks before the repeater dropped out
due to the low battery voltage. (Plenty of capacity in an emergency, I'd say)

Say, just how large is an 800AH, 12V Gel Cell? Where Might I get one to
replace the pair of auto batteries I now have for backup purposes?

Thanks - Rick

> harmonics or noise using one or the other?

The main criteria for mixing involves the image frequencies that are created, and how easy they are to filter out. If you mix .5 and 9.5 MHz, you'll get 9.0 and 10.0 MHz, which are a bit close for filtering. On the other hand, 4.95 and 5.05 will theoretically give you .1 and 10.0 MHz, which would be easy to filter. However, if you go too far in this direction it doesn't work (i.e. you can't get 10 MHz by mixing 5 MHz with itself!) A good rule of thumb is to aim for an image frequency about 50% off your desired frequency. That would mean mixing 2.5 and 7.5 MHz, giving resultants of 5.0 and 10.0 MHz.

In the 1976 catalog from a german part supplier (Schuricht), I can find
this tube at a price of approx. DM 1630,-- + tax.

From: wheeler@cts.com
Message-ID: <wheeler.45.004B47CF@cts.com>
Source record: 113265

Is it still possible to get a prior year ARRL Handbook? Such as '93 or '94? What was the first year that it went on a diet and lost all that weight? My last one was '88 and I want a newer one but the '95 one that I saw did not have anywhere near as much construction articles...

regards
KB7PT

1725. misc homebrew stuff fs

I have some items that may be of interest to
homebrew types.

a couple dozen ten turn pots (2k) with dial counters.
the counters are duodial series 2600 made by Helipot/Beckman.

a couple dozen N fem-fem bulkhead connectors

about 50 bnc crimp style connectors for rg-58

3 open-frame 12v, 1.5a power supplies, still wrapped

a dozen 4" by 6" boards, 22 finger edge connector (per side)
gnd plane on one side, pwr and gnd busses on the other.
Douglas model # 12-DE-6GP

a dozen N connectors, the standard 7 piece types

a dozen bnc male to pl-259 adapters

a couple dozen bnc tees, both _ _ and |-
| "
"
(sorry for the poor ascii art)

75 feet each of 1/2" braid and single aught stranded,
the latter is pick-up only in the San Jose area.

posted for a friend who's news server is down, email
any interest to beavis@io.com, thanks

>intermod? I don't need to get rid of it all, just cut it down
>significantly to let the repeaters through on a couple frequencies.

I have the same problem except my interference is from the city's
fire & police communications center (150MHz) located 1/2 mile from
the house, rather than from pagers (152MHz).

Digi-key sells a Helical Filter for 2m -- tested at 145MHz with 2.8
MHz bandwith (+/-6 MHz down 25db) with 8db loss. Would that help if
inserted between the antenna and radio or is the problem in the
radio. (Yes, I do have the wide receive turned on; I know, there's a
price for everything).

>
>Pierre Thomson | mmommsen@mhv.net | wcrest!pierre@kd3bj.ampr.org

Sigh, .5 is hardly a value you want. It is easy to separate out 5MHz from 2.5MHz and 7.5MHs. But is it at all easy to separate out the second harmonic of 2.5MHz from the 5MHz desired signal? Even in a frequency synthesizer design this kind of spurious will give you problems at some precise frequencies. (How precise depends on the loop bandwidth, sampling frequency, etc etc. For example were the 5MHz to be divided by 100 and used in a PLL and the ACTUAL frequencies were 2.449MHz and 7.5MHz giving 5.051MHz plus a weaker spur at 5.00MHz you'd have a noise spur into the phase comparator at 1KHz. (The divider aliases the 51KHz away spur into a phase noise term in the divider output.)

In designing conversion schemes examine potential mixer spurious from the 0th harmonic on both signals (zero frequency) through about the 13th (depending on just HOW FAR down you insist spurs be) on BOTH signals into the mixer. Then either characterize the mixer yourself or trust manufacturer data sheets if you use Mini-Circuits Labs or the like. Check for all spurs that cross your passband and make sure they are low enough on the spec charts. Otherwise you are in for nasty surprises like that second harmonic of 2.5MHz in the example you gave.

: Any advice or info would be much apreciated...
I'm not sure how much you know, but I have done similiar thing with the highband Mastr II. If you have a low band mobile version of the Mastr II, you will need to remove the transmit switching relay and install an additional RF connector for the TX RF out. You need to enable the rx to recieve when the rig is in TX mode. Check at oak.oakland.edu in pub/hamradio/mods/ge for additional information. There are also files detailing the conversion of micors in motorola directory at oak which might also provide you with hints. My highbank Mastr II has worked excellently. I don't have the UHS preamp, but an outboard preamp is a great improvement and should be considered for your low band Mastr II as well. You might post the group on your progress, I have considered converting a lowband version as well.

As far as separation, unless you have 6m duplexers, your only other options are two antennas with lotsa separation or either separating the Mastr II tx and rx sections or have 2 Mastr IIs, 1 for receive and 1 for tx and have a split site and use rf link between (very common on 10m).
Good Success & 73!

Its quite feasable, but you will need the appropiate software. Since not all spectrum analysers are the same, it must be written for the analyser. I doubt software written for an HP would control a Techtronix instrument.

If anyone has software that would control an Anritsu analyser, I too would like it.

>
>Archie (KX5X)
>

Yes, but there is a lot of hardware built onto that little 8031 chip, and
several places have them on sale occasionally; they aren't that expensive.

Since it has the serial port, parallel port, timer etc. all on one chip,
it really saves space. I built a darkroom timer a while back that was on
a 3"X3" board. And a controller for the Fred Williams direct digital
synthesizer that was on a smaller board than the original Z80 version,
and had a few more features. Both with the 8031. That's why they called
it a "microcontroller".

Both have their advantages and disadvantages. Probably one disadvantage
with the 8031/8051 is the TIME you have to put into it. I don't think any
project I've built with it has cost more that $30. But radio amateurs are
supposed to be inventive and good at making a $300 device cost $30 !

The task of buying cores seems to partition into two paradigms:.

You can buy one for $32.

Or you can buy a million for 32 cents each.

There seems to be no middle ground. Yes, indeed, you will find everything
at Dexter expensive in small quantities (they have to make money).
Here at HP, we tried to buy quantities of 100 and 1000 cores from TDK's
distributor in NJ and got laughed out of their order processing department.
Let alone try to go directly to TDK. At least with Dexter you can place
an order at some price.

It's a lot more cost effective to cruise your local surplus store or
catalog and buy a switcher. Unless you want to learn how to build
one, in which case $32 is part of your "tuition".

I don't know anything about capturing HPIB output on a PC (I assume this this part is straightforward if you've got an IEEE-488 interface card), but there is an EXCELLENT shareware HPGL viewer/printer program available from Ravitz Software, Inc. called PRINTGL. It can be found on many BBS's in amongst the graphics software. It is also on the Dr. Graphics CD-ROM from Accurate Research, Inc. PRINTGL is outstanding.

I've been following some of these threads on purchasing parts
from manufacturers and am now wondering if there are any
"homebrew clubs" where people get together and order
medium quantities of a variety of components at volume discounts.

Sounds like it could be a good idea. And if there are organizations
like this in the San Jose area, I would be interested in joining.

The ARRL Handbook has a good section on toroids. It tells what the
colors mean and how to calculate the number of turns needed.

If you dont have a Handbook, check with your local library. Ours
has several copies. (And for those of you with older copies,
consider donating them to you local library system -- or better yet,
get your club to donate a new one!)

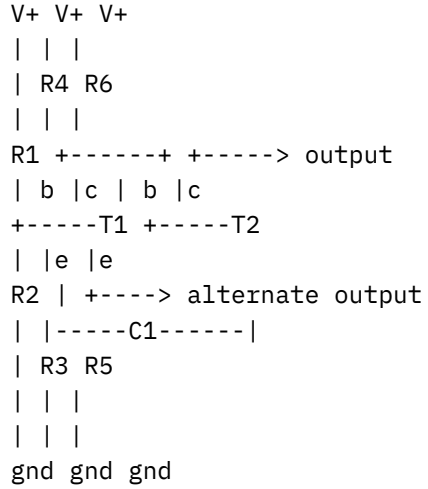
>stability is not over important.
>
>The output I seek is very fast, thin square wave pulses with ajustable
>space ratio.

I once read about something like this and played with it a little:



T1 & T2 something like 2N3904 should work for 20 Mhz (drawn for
NPN transistors, depending on the frequency you want almost
anything might work..)

Try something like R3 & R5 = 1K, use R1 & R2 to set the bias on
T1 (1 to 10 mA?), then select R4 to set bias on T2 to about the
same collector current.

You can use the output or omit R6 and use the alternate output
from T2's emitter.

The frequency is controlled by C1 (and R3 & R5). You can vary
the weight (mark/space) by varying R3 and R5.

Note that none of the transistors should saturate. If you want
to run higher in frequency, build it on a ground plane, use
higher frequency transistors (2N5179?) and lower resistors for R3
and R5.

>
>EBRATCHER@aol.com

I don't know of any legal "boosters" or "add-ons" other than a variety of antennas for mobile use. Boosting the power would only give you barely noticeable performance over getting a clear line-of-sight view of the cell phone tower. I've found that in our area (Oregon, Willamette valley) that in the outlying areas where cell phones will not reach, that most of the time I can call up a local HAM repeater and either use the phone patch, or ask someone to make a collect call to let my wife know that I will be camping for an extra day, etc.

Without trying to sound like one of those "net police types" I would caution against trying to modify a cell phone for more power on the cell phone band. It is not only illegal, but probably won't help tremendously since that would only give you one-way performance.

Good luck,
Ed Burress

1753. Homebrewing your own cabinet

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-03 00:00:00 UTC
From: billhar@spaceworks.com
Message-ID: <D80vzu.7up@spaceworks.com>
Source record: 113154

Forgot to put a subject line on the first posting.

In a earlier posting we learned how to homebrew a transistor. Now here is a novel new material to build the cabinet for your new rig using those homebrew transistors.

Radio News - February, 1925
PICTURE: Young man with a radio receiver, approximately 18 inches long 5 inches high and maybe 5 inches deep. Five dials on the front panel. The finish on the radio has a marbled effect.
CAPTION WITH PICTURE: Sour Milk was the material employed by Mr. L. Abrams of New York City in building the novel set shown above. He constructed the cabinet and the dials from sour milk, coloring it with dyes before it hardened. Mr. Abrams will gladly pass the formula along to any other radio fan.

And I bet he made his condensers out of "condensed" milk, pilot lamps out of flower "bulbs", and he used "spaghetti" over his wiring.

I can hear Mommy now, "Sorry honey, we haven't any milk, Daddy is building a new radio". And Daddy, "Hey kids! Keep that cat away from the radio!"

And I hope that next hombrew project doesn't call for a 1 farad air variable condenser. Have any idea how big it would be? The values we are used to dealing with in radio are in the micro, micro-micro, and pico farads, one microfarad equaling 1/1,000,000 of a farad. According to Radio News for October, 1925, a 1 farad condenser would stand 792 feet tall, with 117,300 plates spaced 1/25 of an inch apart, 1/25 inch thick, and the area of each plate would nearly equal the ground area covered by the famous Woolworth Building.

Just think of the size of the knob you would need. Try getting that into your sour milk cabinet.

Crystal filters at 70MHz could be quite narrow (15KHz), and then the
image poses no problem. I have a feeling that one company (perhaps
JRC) uses a direct 70MHz to 455 KHz conversion.

Perhaps one reason for unpopularity of that conversion is that 455KHz
filters are more expensive than those at 9MHz. Also, an extra
conversion allows for passband tuning and cheaper RF speech
processing. Many top rigs have yet another conversion to 100 KHz,
most likely to make the notch filter effective.

You noticed that omission, too, huh? I remember reading that section of H&H and wishing those guys had given the subject a little more in-depth treatment.

Unless someone out in sci.electronics-land can supply the answer, the only thing I can think of doing would be to start writing equations (sigh...). Either that or SPICEing it to get an approximately optimal distribution of feedback ratios among the two paths...

1760. Superhet receiver question. Why a triple conversion?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-04 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995May4.161009.40092@ucl.ac.uk>
Source record: 113074

In a double conversion superhet, one gets the advantage of decent image rejection and good selectivity. In order to get the best image rejection, it seems sensible to run the 1st IF at a very high frequency (say 100MHz) and for best selectivity run the 2nd IF at a very low frequency like (say 500kHz).

I've heard it said that you should *not* change the frequency in a mixer by more than about 10:1, so mixing the 100MHz IF with a crystal oscillator at 100.5MHz, to get a 500kHz second IF would not be sensible. Its more common to introduce a third conversion stage with a first IF of say 100MHz, a second of 10MHz and a third of about 500KHz.

Clearly a double superhet would be cheaper/easier than a triple, so what is the reason for not changing from 100MHz to 500kHz in one go? Why convert to 10MHz first?

Perhaps its because the 100.5MHz oscillator could leak into the 100MHz IF chain. That my best guess, but would appreciate any comments.

In a research project that is occuring in my university department (nothing to do with superhet receivers), a colleague mixes 200.000MHz and 200.010MHz to produce an IF of 10KHz. I'm not aware of any problems wth this.

In an HF receiver (2-30MHz) with the typical IF's of 10.7MHz and 455KHz, the conversion from 10.7 to 455 requires an oscillator at 10.225MHz, which falls in the coverage range of the receiver, I doubt its possible to receive anything other than the internal oscillator on 10.225MHz. If however the first IF was at 100MHz, and the second at 455kHz this problem would not exist. I must be missing something.

Hi, not sure about radar detectors, I guess you may be able to use them.
Another inexpensive way to get into 10Ghz is using surplus Alpha Microwave type
Gunn diode assys from commercial motion sensors and door opener systems. You
can usually find these at hamfests for $10 or so. You modulate the Gunn P/S to
generate wide band FM. They include a mixer diode, which you can couple to your
FM reciever as an IF. It's a good idea to shield the FM recvr, and use a
preamp of some sort. Without AFC, you'll need the fast tuning of a broadcast
reciever to find and track the signal. It will drift a lot! I have tried using
a 2M IF and it is tough.

You'll need to tune these down a bit - they're usually at about 10.525Ghz. They
can be course tuned by a screw protruding into the cavity, and fine tuned by
varying the Gunn diode voltage. Using a system like this at both ends, you can

run full duplex. But the transmit freqs need to be offset by the amount of the IF. There have been many articles written up in the magazines over the years on how to do this. In older versions of the ARRL handbook, there were some, including a nice one by Glenn Elmore on a 2Mb/s 10Ghz data link. The new handbook dropped these!?!? Also, the RSGB VHF/UHF manual has some good stuff.

There have been some good articles published in QEX lately by Paul Wade - N1BWT(?) on uwave antennas. It's fairly easy to build up, say an 18dbi horn for these using his info.

Oh and another note - these are not Gunnplexers. Gunnplexers contain an additional varactor for a seperate tuning scheme. You run them with a fixed regulated supply and tune using the varactor. With the Alpha's, you do it all by modulating the power supply (LM317's work well).

Have fun!

I'm not sure about used RADAR detectors, however there is a gentleman
in CT that sell Gunn oscilators for $25 a pair. Add a few junk box parts
and a cheap FM transistor radio and you can start playing with WBFM.

Those interested can e-mail me for more info.

: Jim

Anyone can make a DF unit with a few thou. Just put a small GPS unit in a
box, along with a transmitter. The transmitter continuously gives out its
location, and even elevation. Any small calculator sized box can hold a
receiver that will pick it up. So I lied, it's actually an absolute
position transmitter. GPS units are under a thou, but I don't know if
those will have the interface to put out the info.

The narrower and more restrictive the group topic is, the less support
it will have. QRP is well understood and has lots of interest. Heck,
even I'm interested in QRP, and I have 75 acres in the country. Let's
keep the name short, sweet and well understood.

Forward (and backward) slashes are "forbidden" characters in newsgroup names. The reason is that all news server software sooner or later has to access files and directories, and since the usual convention is to map the dot-delimited components of a newsgroup name into subdirectory names, the slashes could possibly be misinterpreted by the operating system as directory-name separators.

I am more intrested in a simple transceiver design. Besides, the 33 cm
band isn't too crowded ! %^}

|> Any thoughts on how to add AMPS to a dual band HT or mobile rig guys?
|>

|>
|> Mick
|> AC6EU
|>

Probably could pull out the code, look at the algorithm and try to re-apply
it somewhere else. I simply want a 33 cm transceiver that can be made
cheaply and fairly easily.

That's one problem, which can be avoided by good balanced mixers. Much harder
to avoid is failing to receive the 99.5MHz image frequency. LC circuits with
60dB of suppression outside a 1% width just aren't physically practical.
And in a typical HF rig that converts up to 100MHz, the first IF is 30MHz
wide, meaning your image frequency is guaranteed to show up in the passband.

>In a research project that is occuring in my university department (nothing
> to do with superhet receivers), a colleague mixes 200.000MHz and 200.010MHz
> to produce an IF of 10KHz. I'm not aware of any problems wth this.

If this gadget is entirely sealed, so that there is no signal whatsoever at
the image frequency (either 199.990MHz or 200.020Mhz, you didn't say which was
LO and which was signal), then this is perfectly fine, because you don't need
image rejection.

>In an HF receiver (2-30MHz) with the typical IF's of 10.7MHz and 455KHz,
> the conversion from 10.7 to 455 requires an oscillator at 10.225MHz, which
> falls in the coverage range of the receiver, I doubt its possible to receive
> anything other than the internal oscillator on 10.225MHz.

If the IF chain is in a sealed box, leakage from the internal oscillator can
be kept to a reasonable level.

> If however the first IF was at 100MHz, and the second at 455kHz this
> problem would not exist.

This would present insurmountable image problems.

>Norm,

>WD2AEM
>cramer@dseg.ti.com

The phones I have seen have incorporated in their design the assumption
that the TX and RX are exactly 45.0 Mhz apart, usually by incorporating
it as the second IF. Also, since it is a full duplex design, the
off the shelf isolation filters are set at the cellular band.

So you are probably looking at a half duplex design.

You will of course need to retune the synthesizers and power amp to lock and
give a reasonably power at 33 cm, as well as have some sensitivity on the
receiver at it's new frequency.

Further, the microcode would have to change since the Tx/Rx changes
for a half duplex design.... maybe take it out completely and forget
about cellular architecture and just use it as point to point, or
on a repeater. (maybe just a transmitter?)

I can see some neat things you could do with one of those three watt
bag phones, and maybe you can just hardwire a bunch of cellphone
handsets to a 33cm frequency...

I am more interested in the cellular / frequency reuse architecture.
I would like to try to add a microprocessor interface to (or have a way
from the manufacturer to) modify the frequency under software control.
maybe add in a few I/O lines to deal with the AMPS chip or two and
have a cellular system built around a 440/144 Mhz design.
(instead of the 835 Tx/ 880 Rx design in cellular phones.)

Any thoughts on how to add AMPS to a dual band HT or mobile rig guys?

>weeks. There are also 2, 3, 5, and 10 Farad versions.

Well, I am not embarrassed as I do know that such capacitors are
available. They did not exist though when the article was written.
Did you notice the date? That was October, 1925. In those days a 2 mfd
paper capacitor was approximately 3/4 inch in diameter and around 3
inches long. The capacitor referred to in the article is an AIR VARIABLE.
A lot of difference there. I don't think you could make a 1 Farad air
variable small or cheap.

If your analyzer has the HPIB interface option, there's a program available called "Icapture" that makes this easy. In addition to the progarm, all you need is a simple cable between your analyzer's RS-232 output and your PC.

The program is available free of charge from HP. I believe their number in Santa Rosa, CA, USA is (707) 577-6801.

There is also a text file on the disk which includes an ASCII picture of the interconnect cable - it's simple, but you will have to wire it yourself.

As a final note, this program does not allow you to manipulate data to or from the analyzer. It will, however, save a snapshot of the screen to several different computer graphics formats.

> at a very low frequency like (say 500kHz).

Each conversion generates an image. When the 100 MHz IF is converted to 500 KHz, the image of the 100 MHz signals will be 1 MHz away. For example, if the desired signal is at 100 MHz and the L.O. is 100.500 MHz (100.5 MHz - 100 MHz = 500 KHz), the image will be at 101 MHz (101 MHz - 100.500 MHz = 500 KHz). It is difficult to achieve sufficient selectivity at 100 MHz to reject this image, therefore, the following IF frequency should be higher than 500 KHz. Note that the degree of image rejection has nothing to do with the selectivity of the 500 KHz IF.

>I've heard it said that you should *not* change the frequency in a mixer by more than
>about 10:1, so mixing the 100MHz IF with a crystal oscillator at 100.5MHz, to get a
>500kHz second IF would not be sensible. Its more common to introduce a third
>conversion stage with a first IF of say 100MHz, a second of 10MHz and a third of
>about 500KHz.

Yes, with a second IF of 10 MHz, the image at 100 MHz will be 20 MHz away. In all likelihood, a modern design will then use the 10 MHz IF for some purpose other than finalizing the selectivity of the receiver. For instance, it might be used to provide passband tuning, by using a variable 2nd L.O. that allows moving the 10 MHz IF back and forth across the passband of the final 500 KHz filter.

>In a research project that is occuring in my university department (nothing to do with
>superhet receivers), a colleague mixes 200.000MHz and 200.010MHz to produce an
>IF of 10KHz. I'm not aware of any problems wth this.

So long as there are no signals present at 199.990 MHz (the image), it should work fine.

>In an HF receiver (2-30MHz) with the typical IF's of 10.7MHz and 455KHz, the
>conversion from 10.7 to 455 requires an oscillator at 10.225MHz, which falls in the
>coverage range of the receiver, I doubt its possible to receive anything other than
>the internal oscillator on 10.225MHz. If however the first IF was at 100MHz,
>and the second at 455kHz this problem would not exist. I must be missing something.

So far as I know, image rejection is the only reason for not converting in the manner you've suggested. You're probably correct about "hearing" the oscillator, which is why multiple conversion receivers nearly always have birdies. This is particularly true in general coverage types, because there are no "unused" frequencies.

I didn't see the original to this thread, but FYI I've tried the following:

When I rode the Lewis & Clark trail in the Bitterroots last fall, I had a 5/8 connected via an NMO mount on a rack I put on the back of my mountain bike. I threaded the coax up to the handlebars and into my handlebar bag. In the bag, I had a Kenwood TH78A (I selected it especially for its mountain biking characteristics) with a gel-cell battery (3 amp hours, good for 2+ days of riding) and brought out a speaker mike which just clipped on the bag. I was the relay point for the group, with my big antenna. It worked rather well, given the difficulties of the terrain (i.e. lots of mountains, hills, etc. which hid signals, caused multipath echoes, etc.) Each ham member also carried a roll up J-Pole that we home brewed, in case we got separated too far and needed that extra oomph.

On or lesser trips, I just remove the rack and 5/8 wave, and still the 78A in the outside pocket of the bag and use a 10" rubber duckie. For 1/2 to 1 mile coverage over hilly (not mountainous) terrain, it works fine in the group.

I have a headset, and have carved out my helmet to accept the headset, but have not tried it on a real ride yet.

1796. re: cb to 10 meter conversion

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-05 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <b5e_9505050530@mba.mba.org>
Source record: 113097

parkerbk@sd2.af.mil (B. KEITH PARKER) wants info on converting a Dak mark 9 to ten meters.

I've never seen anything about this specific rig. Over the years, more around the time when CB was expanded to 40 channels, there were a lot of articles in 73 magazine on converting CB sets to ten meters. They used to have a list of the articles on the subject, that was readily available, maybe only for an SASE. It's worth checking with them for a start. It might also be helpful to get a schematic of your rig, though I have no idea where it can be found. There are the standard places to look, such as in a Sam's Photofact.

A lot of rigs had the same basic circuit and circuit board, put in a different box and with a different name. Get a single schematic, and it just might apply to your particular rig. Likewise, if you can find out what other rigs are like yours, you're more likely to find someone who's already converted it than to find someone who has converted exactly the same rig.

One point about conversion. When CB to ten conversion was in its prime, primarily because the CB sets were available real cheap, the synthesizer IC's used in them allowed for relatively easy conversion. I've read that later rigs used an IC that did not allow for easy conversion, or perhaps did not allow any conversion. The idea, of course, was to keep the rigs on CB instead of someone converting them to some other frequency for illegal operation. The side effect was that it was hard to convert to legal use on ten meters by amateurs.

I found a couple of CB sets in the garbage about a year or so ago. One used a 455 KHz IF, and was crystal controlled. NOt too useful. The other was a forty channel synthesized rig, but it did not use the IC that allowed for easy conversion. I haven't put much effort into reasearching the matter, but from the pinout of the synthesizer IC, it does not look like it is a candidate for conversion.

Too bad it wasn't an SSB CB set; they have plenty of potential that would make conversion worthwhile.

That brings up an important point. Open up your CB set, and look for the synthesizer IC. Either it's the only one, or 1 of a handful of IC's. It's most likely the one with the most pins, too. If you can send out another post with more information, including that IC number, you're more likely to come across someone familiar with what's needed to convert it. You can also look up the IC in a replacement semiconductor guide, and get some information about possible converstion by looking at the pinout of the IC.

I hope this helps you to find some more information.

Mark

If you only need one of these you might want to think about winding your own. Its not as hard as it sounds and there are a number of articles in past radio magazines issues which I could send you a bibliography on once I get back home to check my files (I'm on the road right now). I have done this a couple of times in the past with good success using and older surplus transformer core as the starting point. Its not as hard as you might think.

This is correct. If you don't know where the core came from, don't trust the color. Wind 5-10 turns on it and measure it, either with an LCR meter (a great help for anybody who buys strange stuff), a GDO, or just put it in an oscillator with a fixed C and measure the frequency (another use for general coverage receivers).

[deleted]

I think the cabinet would have been made from casein, one of the first
plastics. The raw material for casein actually was milk. BTW, I think
germanium was extracted from soot a long time ago.

1 F capacitors have actually been available for some years. They are
made using an electrolytic process, and are used for memory back-up
sometimes, in place of batteries.

instrument output into a dos file .

>Does anybody know if with the hpib interface there is somebody
including with it some software , I mean program already written that
capture the output of such interface in a file and then let you display
it.<

Roberto:

I'm not particularly fluent with DOS machines with HPIB I/O, but I routinely use many HP instruments controlled with HP computers running HPBasic. I usually buffer/modify the HPGL data from HP8566, HP3577, HP3585, HP8510s, etc. by reading it onto the computer rather than directly dumping from the instrument to the plotter. This way, I can rescale, rotate and annotate the plots.

I don't know much about HPIB cards for PCs. I have an old National Instruments card that I haven't used because the documentation is extremely poor (MHO) and not nearly as friendly as HPBasic. If you have an HP computer, you can get a demo copy of HTBasic which will run on a PC and allow you to read (but not write) HP disks (LIF). This would allow you to get the data via the HP computer and import to a PC for whatever purpose.

Hope this helps.

Just trying to keep this article alive. There is a good project for this in May 95 73 magazine. It does lack some things though. I would think using a small amperage power supply could be used to cycle on and off to charge the batteries and also have a second 20 amp power supply turned on when putting out 100 watts on the HF rig. The 20 amper would be turned on manually. Run off the batteries for vhf if you've got a packet station running. just an idea!

Dave Kirby (G8WRB) asked why there are triple conversion recievers.

Dave:

One reason that you won't see a double conversion from 100MHz first IF to a 500KHz second IF is partly what you surmised. The LO can leak into the first IF even though it is out of band.

Typical high IF filters are called "roofing filters". They are very broad (on the order of several hundred KHz wide) crystal or SAW (surface acoustic wave) filters. They also typically only have a few poles, so the skirt selectivity is modest. The image problem comes back when you move the LO so close to the pass band of the filter. This would especially be true for an IF on the order of 10 KHz.

With crystal filters in the 5 to 10 MHz range "easy" and "inexpensive" to make the only reason to go to a REALLY low last IF is to keep the BFO out of the band of interest. It seems to me that you SHOULD be able to build a sufficiently shielded BFO/detector assembly so that leakage is not a problem. Of course, for a manufactured, unit that translates to added expense. It is easier and cheaper to manufacture if your design doesn't have the potential to interfere with itself because you chose non-interfering frequencies.

Again, in my opinion, the reason you see a lot of the selections made in commercial equipment is to make it easy to manufacture ata reasonable price with reasonable performance. You would design a radically different receiver if ultimate performance were the goal.

Perhaps Zack Lau or Ulrich Rohde are listening in and have some other ideas. They both are much more expert in this field. Look for QST and Ham Radio articles by Ulrich. I also believe he has written a book or 2 on the subject.

Please stop suggesting rec.radio.amateur.qrp - there's already a very
fine qrp email list with a high S/N ratio. Last count there were
400 subscribers. Now that doesn't sound like enough to warrant
a newsgroup, does it? In the past 3 years every time a suggestion
was made to shift from an email list to a newsgroup the suggestion
was always vehemently voted down.

If the low-profilers want a group, then why not start an email list?
Such lists are very very successful, for they target a select-interest
group and as a result the noise level is quite low (no flame wars).

With well over 7000 newsgroups some sites may have reached the saturation
point and choose not to subscribe to the new rec.radio.amateur.low-profile.

It is also possible to identify the type of material the core is made from with a little experience, simply by feel and looks. this method is not 100% but I have been able to indentify using this method at about 90% or better. By doing this you would then be able to understand what frequency each colors are recommended for as well as other information.

1812. Ramsey 6 meter kit

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-06 00:00:00 UTC
From: curt182@aol.com
Message-ID: <3oh851$nsi@newsbf02.news.aol.com>
Source record: 113021

Help, I'm stuck! Your assistance for a newbie would be greatly appreciate.
Reply to curt182@aol.com

I'm assembling the 6 meter FM transceiver and I'm confused about the
installation of the diodes for the RECV, -RPT, +RPT matrix bridges.

(1) On page Assm. 59, H42c, the RECV row is: []8 []64 []256 []512
[]1K []2K []8K
(the assembly sheet also shows this)

the below H42e's diagram shows 16, 64, 256, 2K, 4K, 8K respectively

If you are going by the holes on p. Assm. 58, H41 illustration it is also
16, 64, 256, 2K, 4K, 8K

Which is it? I'm using 16, 64, 256, 2K, 4K, 8K.

(2) Despite scrutinizing for solder bridges, loose connections, making
sure the diodes are in correct, etc., and going over the whole thing 3
times I still have these problems as well:
a. I have the unit programmed for 52.525 MHz simplex for testing
purposes. But when I turn the set on the transmitter diode lights up and a
carrier, but no audio, is present.
b. No squelch.
c. Intermittently my audio could be heard in earlier testing, now it
doesn't. Voltages at test points seem to be what they should be.

Any help would be appreciated! Despite these problems, I'm having a lot of
fun putting this together!

Thank you for your time and attention.

The Plessey SL6700 is a pretty good AM receiver IC, it can also be used for SSB modulators and other functions. The only pitty is that Plessey in their infinite wisdom, since being taken over by GEC have discontinued it, about 2 months ago. There are now decent AM ICs available at all! If anyone knows otherwise, let me know.

Don Johnson, in his book "40 Years of HF Mobiling" describes an automatic
antenna tuner which I built and found it works quite well. Basically it is
just a phase detector which senses current which is out of phase with the
voltage at the base of the antenna. Depending on which way it is out of
phase, a motor is driven to tune the antenna back to resonance. Today's
rigs are a lot more sophisticated, using a microprocessor to remember the
settings for various frequencies and also adjust C as well as L, but the
basic concept is the same.

QST for October, 1982 has a schematic also.

Source record: 113024

Please can anyone help with some hard data on the Qs of hand-wound coils, such as might be used for antenna tuners?

If you can't use B&W Miniductor (not available in Europe), what's your favorite method of winding large coils for ATUs and PA tanks?

Is there any information on Q degradation caused by using plastic drainpipe (probably PVC) as a former?

Crystal filters at 70MHz and higher are not all that temperature stable. You do
not want to try to generate a 100dB image rejection with such beasties as you'd
need to cascade several. As temperature varied your filter shape would degrade
giving you excessive losses in yuur first IF.

>That's one problem, which can be avoided by good balanced mixers. Much harder

Balanced mixers help. They do not solve. Balanced mixers you can generate economically typically have a "balance" of about 40dB. (LO and signal leakages are 40dB down from the converted signal - roughly.) This also does nothing for the image frequency rejection at 1MHz away from your desired signal. Even this is "difficult" to filter to an acceptable degree at 1% away from the desired signal, even with reasonable crystal filters.

>>In a research project that is occuring in my university department (nothing
>> to do with superhet receivers), a colleague mixes 200.000MHz and 200.010MHz
>> to produce an IF of 10KHz. I'm not aware of any problems wth this.

This ought to work "reasonably" well as long as your collegue has considered all aspects of spurious conversions. (Usually you can get away with this if there are only the one signal and one LO frequency, say in a frequency synthesizer loop or a frequency comparator. In the synthesizer case - watch for the image, of course.)

>
>>In an HF receiver (2-30MHz) with the typical IF's of 10.7MHz and 455KHz,

>> anything other than the internal oscillator on 10.225MHz.
>
>If the IF chain is in a sealed box, leakage from the internal oscillator can
>be kept to a reasonable level.

You DO want to filter the begeezus out of it and place the IFs in a very well shielded sub-enclosure.

>
>> If however the first IF was at 100MHz, and the second at 455kHz this
>> problem would not exist.
>
>This would present insurmountable image problems.

One other advantage a third IF can give comes from lower gains at any given frequency. This makes avoiding regeneration in the IF a lot easier. (However my old "dream receiver" used up-conversion to the 150MHzish range with a mono-lithic crystal filter at the first IF for a "roofing filter." Then I down-converted to 9MHz for the final IF. Since crystal filters at 9MHz are stable enough to be used as the entire receiver selectivity (in two chunks of course) there was no huge reason to go to the trouble of a second conversion. Of course the second IF's output had to be *VERY VERY* well shielded from the rest of the receiver lest there be a humdinger of a birdy at 9MHz. NB: The frequency synthesizer also had to be very well shielded from the rest of the system as some of its internal frequencies and harmonics were within interesting signal ranges. But such shielding is entirely possible, if expensive. (Which reflects on why some of the REALLY good receivers are somewhat "expensive" once you tack on profits and margins and the like for manufacturer, levels of distributor, and sales outfit.)

(Example that the shielding IS possible: There is a box on the GPS satellites. It accepts 10.23+delte Mhz input from any one of N sources. It contains three parallel frequency synthesizers for ultra reliability. The outputs are all in common and feed a pair of buses feeding each module on the satellite with 10.23 + epsilon MHz. In order to meet the specification for phase noise this silly puppy, with step size on the rough order of one part in 10^13th (no fooling) had to have at *LEAST* 100dB input to output isolation at 10.23Mhz. I told the designers to design goal at 120dB and hope for 100dB because at 80dB it was so far out of bed that "fer shure" even the DoD inspectors would see it. To his credit the actual hardware designer took my block diagram and produced such a device. I'd suggested a large (I mean *LARGE*) number of grounding wires. He designed them in. It worked..... Then production tried to "value engineer" the puppy. They took out most of the ground wires. They did not get it working until they very carefully replaced nearly all the ground wires from the substrate to the expensively hogged out cavity in which it was installed. So it CAN be done; but, you REALLY REALLY have to do your grounding and shielding analysis.)

How about rec.radio.amateur.covert? :-)

The point of the low-profile argument is that you don't want everyone knowing that you're an Amateur (whether it's because you're contravening apartment regulations, or to avoid drawing the attention of burglars etc.) Mind you, the "covert" also suggests clandestine third-world stations...

!Brand New! Wavetek Model 1034A Microwattmeter, sn #1810024, and
a Model 13780 (1 MHz to 18 GHz) Power Sensor probe, sn#14-1713.

The 1034A has a mirror-backed 4.5" meter, indicating power on three
scales: from below -40 up to +10 on a dBm full scale, -11 to 0 dB, and 0
to 1. Eight switchable decade ranges go from below 10nW (-50dBm) to 10mW
(+10dBm). Front panel zero and +10 dBm calibration outputs are available.
A calibration factor adjustment nulls the meter and adjusts +-1 dB to
account for the sensor probe.

The unit is in a flip-top gasket sealed grey metal case. In the flip top,
the power cable and probe are stored. It runs on built in NiCd batteries
or the power cable. Packed up and ready to go, the unit is 9" x 6" x 8",
and weighs 10 lbs. Batteries and the probe check 100% operational.

Knobs, button, etc include: the meter, a 50/75 ohm selector switch,
115v (50-400 Hz) plug in, fuse, power button, calibration factor, 1.1v fs
output that corresponds to the meter reading, a calibration output, the
probe input, and 10 push button switches.

Frequency ranges and accuracy specs for probes, plus calibration data are
included on a custom printed calibration sheet for this meter/probe combo.
Two brand new Operation and Shop Maintenance Manuals are included.

The military paid $1202.00 for this unit back in 1988, and never used it.
I'm asking for $295, and I'll pay postage. Email or call 509-244-3764.

Hello allow me to introduce myself. I am Milton Lord the "Radio Doctor". I can assist amateurs with their technical problems through the use of my instructional videos and 22 years of experience in repairing RF communications equipment.

I have owned and operated a business called HAM REPAIR CO. for over 10 years. With my experience both repairing amateur radio equipment and instructing amateurs I have compiled 25 amateur radio instructional videos.

These instructional videos are designed to give you a better understanding of the technical aspects of your amateur radio equipment.

Whether your desire is a better understanding of packet or the IF alignment of a Yaesu 101 you can find the help you need in one of these instructional videos.

Recently the videos were evaluated by WB6NOA Gordon West and printed in 73 magazine. Mr. West had the following to say.....

.....And Lord knows what he's doing-you see every step in disassembling and reassembling printed circuit boards, and he gives you valuable hints on how to keep from accidentally ripping out solder traces, or inadvertently shorting something out when you accidentally lay the fold-out board down incorrectly.

After screening all of his videos, including a powerful set of tapes that describe how to tune up a kilowatt amplifier, how to pull packet RX out of most mobile 2 meter transceivers, and why the proper ALC settings are important to good linearity, I was convinced we really have someone sincere about producing good videos for getting things done, as opposed to simply a lot of videos to turn a quick buck. He works on these rigs on a daily basis and you can tell it by watching his techniques.

"HAM REPAIR CO."
Kennesaw, Ga.
(404) 422-1415

Specializing in the repair of assorted Ham Radio Equipment.

I would like to invite you to visit my web page where extensive information may be obtained about each video and other services my company provides at the following address...

1830. WANTED: Transistor Specs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-06 00:00:00 UTC
From: rtyo@en.com
Message-ID: <3oftmo$6qp@antares.en.com>
Source record: 113117

I am searching for transistor specs for two MOSFET devices used in the front-end of the Kenwood TS-820S. They are: 3SK35 and 3SK41. If anyone has any pointers on where I can find such specs, I would greatly appreciate it.

73's,

1831. Creator of REC.RADIO.AMATEUR.LOW-PROFILE!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-07 00:00:00 UTC
From: Adam O'Donnell <adam@libertynet.org>
Message-ID: <3oh66v$l28@netnews.upenn.edu>
Source record: 113032

Hello there!

I am the creator of the newsgroup.
You will be able to vote for it in less than one week.

Once Friday rolls along, I will post a Call For Votes, or CFV.
In there there will be all the necessary information on how to
vote for the newsgroup.

Thank you and I hope that you vote yes.
Reminder: If voted down, I will have to wait 6 MONTHS to re-propose
the idea. It is too late now to change the name. I asked about the
name about 2 months ago and the majority said "LOW-PROFILE".

Please vote yes!

72, 73

1832. Re: Automatic Antenna Tuning

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-07 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <60c_9505070430@mba.mba.org>
Source record: 113033

edbu@sepia.wv.tek.com (Ed Burress) in replying to someone else's post asking how automatic antenna tuners work, wanted to know how to do this at home.

Over the years, there have been automatic antenna tuners described in the various ham magazines. I don't have any references at hand, but they are out there. I think maybe they've tended to be for a single band at a time, though I might be forgetting, and would tune things properly as you tuned across the band, but when you changed bands you'd have to do something else to move things to that band. Just like getting out of your car and changing the trap on a mobile antenna.

Automatic antenna tuners are basically a servo loop. SOme sort of sensor is placed in the coax to the antenna, and the output of it goes to a controller that tunes the variable capacitor. I guess there are a number of things that could be sensed. Say it watched SWR (and I do not know if that is what is being watched); when the sensor read lowest SWR, the controller would stop and so would the variable capacitor, and the thing is tuned for lowest SWR.

Some of the commercial tuners probably cover the whole Shortwave band, from 3 to 30 MHz. Most manual tuners would require a change of inductance and maybe even capacitance over that range, so these tuners probably would have relays to switch capacitors or taps on a coil. With the ham bands only, though, one could either get some information from the bandswitch of the rig (don't they now have such information on a plug on the back?), or be stepped manually, have simple band pass filters and detectors that would see what band you are transmitting on, and move the inductors and/or fixed capacitors to the right combination for that band.

I recall reading in an ad for one of the commercial automatic antenna tuners that there was a microprocessor inside, complete with memory for selected frequencies (or something like that). That must be a much fancier controller, which measures frequency inside a given band.

I hope this is a start.

From: Michael.Black@juxta.mba.org
Message-ID: <60d_9505070430@mba.mba.org>
Source record: 113034

dave@intnet.net (Dave Zalaback) wants to build an eggbeater antenna for about 145.5 MHz, for Shuttle and Mir use.

I don't know what the ARRL Antenna Book has on eggbeaters; I just checked mine (16th edition) and I don't see them mentioned in the index.

But this was an easy one. The only time I've actually noticed an eggbeater antenna article was in the very first issue of QST that I ever saw. April, 1971. There on page 44 is an article by Dave Thornborg and Les Kramer entitled "The Two-Meter Eggbeater". Contact the ARRL. Either you can get the whole issue, or they will photocopy the article for you for a small fee.

> Please respond via Email mfranks@ais.net 73 de WB9EZB

The topic of PLL's is a big one and can get quite complex depending on how thorough you want to be and how tough the problem is. With the VCO you'll need a phase comparitor, possible programmible divider(s) and ref OSC and low pass filter. Motorola, National, Plessey, among others make IC's that do a lot of the work for you. They also have application notes on PLL's which are worth reading.

There are also a couple of very good books on the topic such as PHASE-LOCKED LOOPS by R. BEST, DIGITAL PLL FREQUENCY SYNTHESIZERS by U. Rohde and PHASELOCK TECHNIQUES by F. Gardener.

GOOD LUCK!
I would recommend
reading the application

Hi pete

I could not find a search feature on your web page. There was a long unformated list or index. The folks at QRZ cd-rom have a callsign look up search and they have lots of amateur radio files and programs to down load.

Please provide a service to this amateur community. QRZ does not advertize here....every one links to them on the web! There is room to compete with out filling every radio news group with pointers to your off shore order form. Is it a secure server for credit card info?

You're getting closer. The key to 'low-profile' operation is antennas.
Everything else is easily hidden. But the antenna has to be
electromagentically exposed to the whole world, but visibly hidden from your
neighbors. Quite a dicotomy. I think the terms 'secret', 'covert' or perhaps
'hidden' best describe this type of operation rather than 'low-profile.'
Definitely not 'QRP', as this is already well-developed as its own specialty,
and covert stations may be medium or high power if desired. The best antennas
for QRP use are very high-profile, so there would be an immediate conflict in
trying to include this topic in with the QRPers.

[Spelling/grammatical errors cleaned up from previous posting - Sorry]

I was wondering about a recent QST article (by Rohde) where he talks about using a PLL to follow up a DDS, mainly for the purpose of lowering spur levels. If one were to use a divider before phase comparing with the DDS, then it is conceivable a DDS with 20 MHz tuning range could be used to tune a VFO over 0.5 to 1 GHz, for instance, assuming a VCO with octave bandwidth. This seems a lot more convenient than using a bunch of strange divide ratios combined with several switchable crystal references.

I am sure that this has been thought of before, and it may have even been in Rohde's article (although I thought his PLL was running at the same frequency as the DDS), but I am curious as to what others might think.

1843. Re: PEP measurement

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-07 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <3ojagk$7cp@newsbf02.news.aol.com>
Source record: 113044

The FCC defines PEP as "the average power supplied to the antenna transmission line by a transmitter during one RF cycle at the crest of the modulation envelope taken under normal operating conditions".

The FCC allows 1500 watts PEP output on all modes. In order to operate with full legal power an amplifier has to produce 1500 watts PEP, or 1500 watts of short term steady carrier output. Almost any amplifier produces slightly more PEP output than long term carrier output because the power supply sags slightly on sustained carriers. If you load your amplifier up to 1200 watts on CW and flip over to SSB, you may see 1500 watts PEP without undue distortion.

Peak envelope power (PEP) is often misunderstood. To show how far reaching this problem is, in the mid-eighties Nye Viking actually designed and calibrated some meters in tuners to indicate 1.414 times the average power when flipped from the average to the peak position!

I'm not aware of ANY meter that can absolutely determine this power on amplitude changing modulation modes like SSB or AM. But some do an almost perfect job on voice (the most expensive Bird, Coaxial Dynamics, and H-P meters), some are fairly good but not totally accurate on voice (the Bird 43P), and many are relatively poor to pretty bad. The poorest ones mostly include meters in antenna tuners (even the bar graph meter displays) and the one hundred dollar or less amateur radio type wattmeters. When calibrated on a CW carrier and used to read voice, these meters seem to read anywhere from 60 to 90% of true PEP.

PEP has no definable association to sine wave or root-mean-square (RMS) power on amplitude changing forms of modulation (ie. SSB, DSB, AM, etc.). It has no fixed ratio to the average power on these modes. You can not use a formula to convert between average and peak voice waveform power on these modes.

PEP is the effective (useful) power at the crest (highest point) of the RF envelope. On SSB, the average power can vary from a few percent of the PEP to over fifty percent of the PEP. Generally, the PEP on SSB is two to five times greater than the average power. On CW (without envelope keying waveform abnormalities) or on other constant amplitude modes (such as FM or RTTY) the PEP is exactly equal to the average power any meter will show.

FCC standards require, if viewed on a scope, that the highest peak sine wave RF cycle voltage transmitted be multiplied times .707 before any E sqrd over R calculations are done. The highest single RF cycle determines the real peak envelope power.

It definately is the Teflon. Teflon is no better than polyethelyne for losses, it just has better physical performance. For example, look up the electrical performance of PTFE insulated coaxial lines, they duplicate the style of standard solid dielectric lines. With no other changes, placing PTFE or any other material in the high voltage, high current path of a small loop antenna (between the plates) any materal other than air or a vacuum substantially reduces the Q and performance of the antenna.

It's just as likely you may need a 1:1 balun, or a backwards ratio balun. Depending on the length of the feedline and the antenna, the impedance can be anywhere from a few ohms to many thousands of ohms. The reactance may also be outside the tuners range! What are the dimensions of the antenna and the feedline length?73 Tom

This is true. But in 1925, a couple of strips of tinfoil, some paper for insulation, a piece of cardboard tubing, and some bees' wax was about the state of the art for capacitors. Can you imagine what a 1 farad tubular cap using that technology would be? I doubt both of us could carry it away.

: PTFE or any other material in the high voltage, high current path of a
: small loop antenna (between the plates) any materal other than air or a
: vacuum substantially reduces the Q and performance of the antenna.

I looked up Teflon and it has a loss tangent around 0.00015, which
means that you can expect a capacitor Q of around 6600, if the loss
is only due to dielectric losses. By comparision, Jennings says
"typically in the order of 1000 or 5000 or higher" for their vacuum
capacitors. Teflon circuit board is quite a bit worse with a loss
tangent around 0.0011. Those circuit board makers have to worry
about things like dimensional stability...

In contrast, the (loaded) Q of a 3 ft diameter loop is "only" about
600 at 21 MHz...

1850. VHF beam antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-07 00:00:00 UTC
From: altman@PROBLEM_WITH_INEWS_DOMAIN_FILE
Message-ID: <3oinao$vt@osceola.cs.ucf.edu>
Source record: 113051

I'm relatively new to ham radio (and am having a ball!), and am currently beginning to homebrew a simple 3 element beam for 2m. I am working from "All About VHF Amateur Radio", by William Orr, W6SAI (a good book, BTW). His design calls for 3/32 to 1/8 inch aluminum rods for the parasitic elements, and 7/16 inch tubing for the driven element.

The problem is that I don't yet clearly understand which things are critical and which are more forgiving. For example, if I use 3/8 or 7/16 inch rods (which I happen to have on hand) how does that affect other parts of the design? Does it affect the lengths or spacings of the elements? Does it affect impedence matching or line balance? At that diameter, do I need to worry about end conditions?

Also, since this antenna will be protected from the weather by being mounted in the attic (yeah, homeowner's association), will it reduce interference to build the boom and mast out of wood? Does this affect the design?

Obviously, I could just go out and buy the parts as spec'd and put it together, but the goal is to learn something along the way.

All comments and suggestions are welcome. Thanks.

1857. need specs for Loral Microwave relay

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-08 00:00:00 UTC
From: chrise@n0jcf.com
Message-ID: <3omj2b$bkr@n0jcf.com>
Source record: 112924
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Just wondering if anyone has access to a Loral catalog. We are in need of specs (power rating, frequency, etc) for the following microwave relay:

080-D13-A1I-3B2

it is an 8PST SMA type relay with 18VDC coil. s/n 2029 9117

Any info greatly appreciated.

Chris

> would appreciate any explanations of how these devices work.

Well, a SGC tuner works like this: There is a pi-configuration LC circuit,
where the L and C elements are actually a bunch of coils or caps
(arranged in values like 10,20,40,80, etc) that can be switched by
relays in various combinations. There are about 6 to 9 individual
coils or caps for each element, so each element can have between
64 or 512 different values. There are circuits to measure the SWR,
resistance, and phase at the input. A microprocessor uses the
output of these to adjust all the relays until a good match is acheived.
Probably the algorithm would be similar to what you do manually when
adjusting a manual antenna tuner. There is also a frequency counter
circuit to measure the transmitting frequency, which is also used by the
algorithm.

When you tune up for the first time, the relays start clicking like
an old pinball machine, and after a few seconds, it settles down,
and the SWR is low.

The frequency and the final settings are stored in a NVRAM, so that
when you later return to that frequency, it will immediately
try the previous setting instead of "hunting".

Note that boats and aircraft with HF radios almost always use these things,
because they are convenient, and require no operator skill to use.

1863. REPOST - SSTV Demod info sought

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-08 00:00:00 UTC
From: david@pitvax.xx.rmit.edu.au
Message-ID: <3okdrs$8kd@aggedor.rmit.EDU.AU>
Source record: 113055

REPOST - Info/Opinions on SSTV Demod sought

I've been having fun receiving slow scan pictures with JV-Fax lately, using the simple op-amp limiter interface. So far, when band condx. have been good, I've gotten excellent pics from ZL, JA, 6Y (Jamaica) and from around VK of course. A highlight was a noisy but recognisable picture from a GW3. It's a real blast! I'm pleased with the results from a modest 386 PC and a $10 interface.

Now I'm wondering how I can improve the demod, to dig out the weaker signals. The limiter I/F has a definate noise threshold - signal tones have to be well above band noise to decode cleanly.

Would results with a discriminator type detector based on tuned circuits be better than the limiter type interface?

Using the latter and Hamcomm to copy RTTY a while back I found error free copy was only possible with strong signals, but when using a demodulator with dual filters and a 'slicer' I could copy signals down into the fades.

I have started to collect bits to build a SSTV demod using LC input bandpass filtering and discriminator. I'll report any progress.

I note that the trend nowadays is to use pulse width detectors after filtering and squaring the signal. My subjective feeling is that an LC discriminator would work better under noisy conditions as its output is detected and integrated - effectively 'filling in' any lost cycles.

With the 1/f type detectors the data is fed to the computer without further processing. A step change caused by a noise spike is as valid as any other data and will show up on the picture.

I'd appreciate any comments from anyone who has experimented along these lines. I suppose DSP will render both these techniques obsolete eventually - but until I can afford a device and the time to learn how to program it I'm happy to spend a few hours winding inductors!

Best 73, David VK3JKP

>about things like dimensional stability...

I think we have over-simplified the problem. Remember that I compared the same style of capacitor with air, PTFE, polystyrene, and polyethelyne. The air was noticably better in this application.

No way is ANY solid dielectric capacitor as good as 6000. Besides, using your method the therotical Q of a vacuum cap is infinite!

I'm not positive we are using the same definitions of "loss tangent". I assume you are using the "tangent of loss angle". It is the power loss of the dielectric divided by the reactive power intensity in the dielectric with a sinusoidal voltage at the operating frequency.

If so, the dielectric factor of PTFE is 2.1. With materials having identical "loss tangents" but one having a dielectric factor 2.1 times higher, the losses would increase 2.1 times. This is because power density would increase 2.1 times with the same value of capacitance. That does not include the detrimental change in "loss tangent" when PTFE is substituted for dry air or vacuum to PTFE.

If I look at the dissipation factor of Polyethelyne and PTFE they are identical. Teflon has a very slight advantage because of a lower dielectric constant (2.26 vs 2.1). That is why PTFE cable has almost exactly the same loss as much cheaper polyethelyne cables, and a foam filled or air dielectric cable has much lower loss than PTFE.

With a higher dielectric constant, the plates in a optimum physical design capacitor would have less active parallel surface area, so the current density and I sqrd R losses would be higher. This also increases unwanted series inductance and requires even more capacitive reactance (less overlapping parallel plate area, less internal capacitance, and more concentrated power in the dielectric).

Anyway, the best way to account for all the variables is to measure the overall performance of a well constructed reference loop with each type of capacitor. I did that, and the best component was a welded plate, air insulated, nearly square butterfly capacitor. Adding PTFE with no other changes (except "un-meshing" the capacitor plates to reach the same tuning point) caused a very noticable increase in bandwidth, loss of field

strength, and increase in drift and heating.

>In contrast, the (loaded) Q of a 3 ft diameter loop is "only" about
>600 at 21 MHz...

How did you arrive at that value of Q? That is pretty close to the Q of the most piston PTFE capacitors I have measured on a HP4191. It is also MUCH higher than the Q of coaxial line capacitors or single layer transmitting ceramic capacitors. Some loop articles suggest using those components!!! If Q is a good apple to apple comparison method and your data is correct, a capacitor Q of 600 would cause a 3 dB reduction in field strength and doubling of bandwidth.

1873. Where to get NorCal QRP Club info, rigs, etc.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-08 00:00:00 UTC
From: wayne@interval.com
Message-ID: <wayne-0805951357540001@burdick.interval.com>
Source record: 113065

Club Projects Wanted

The Northern California QRP Club (NorCal) is actively encouraging its members to submit their QRP designs, including rigs and accessories, for possible consideration as NorCal club projects. Previous successful projects include the NorCal 40 monoband transceiver, keyer and frequency counter boards, and the Sierra multiband transceiver. Next up is the Cascade 2-band SSB-only rig.

To make a successful club project for NorCal, your design should be fairly easy to reproduce and relevant to QRP operation. If it fills a unique niche, so much the better. Eric Swartz, WA6HHQ and myself will be among those reviewing the designs; feel free to e-mail us (erics@cruzio.com and wayne@interval.com, respectively).

NorCal Membership

If you're not already a member of NorCal, you can write to Doug Hendricks, KI6DS (dh@altair.csustan.edu) for further information. Or call Jim Cates, WA6GER at (916) 497-3580.

Membership is free, but the quarterly newsletter is $10. The newsletter, "QRPp," has been called the U.S. counterpart to Sprat, the G-QRP club newsletter.

NorCal Kits

NorCal recently decided--after selling several hundred kits--to turn over its most successful club project kits (including the NorCal 40A and Sierra) to Wilderness Radio, run by Bob Dyer, KD6VIO. Their number is (415) 494-3806.

1874. SSB Generation

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-08 00:00:00 UTC
From: CNS@psimemphis.COM
Message-ID: <199505082142.VAA26227@chaos.magibox.net>
Source record: 113066

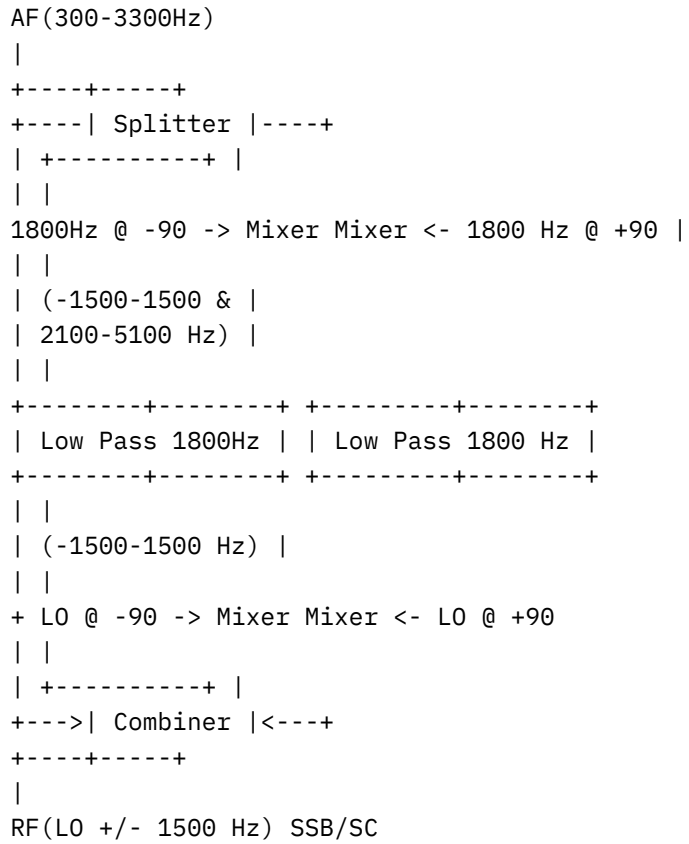
In "Solid State Radio Engineering" (H. Krauss, C. Bostian, and F. Raab, 1980 John Whiley & Sons), there are three methods of generating SSB described.

The first is the traditional SSB Filter IF design:
AF + IF -> (SSB Filter) + LO -> RF.

The second is the phasing Direct SSB (as used by R. Campbell in "High-Performance, Single-Signal Direct-Conversion Receivers" Feb. 1992 QST, and covered in the ARRL Handbook):

AF -> (+/-90 phase shift network) + +/-90 LO -> RF

The third is one I've never heard of (simply called the Third Method):



(when no AF, +/-90 phase cancel each other out -> no RF)

It requires a quadature LO, but it can demodulate SSB as easily as modulate them (just exchange the 1800Hz and LO oscillators). Its benefits appear to be no sharp filters (separation is twice the lowest audio frequency @ low pass filters) and no complicated audio

frequency phase shift network.

Has anybody heard of this circuit or its use? Comments?

Disclamer: Opinions expressed do not reflect the views of my
employer or myself or anybody I know or may ever know.

I just picked up a Tektronix model 2213A scope for a bargain basement price, knowing it would need some repair. Specifically, there's a bad distortion in the trace at about 80% of the way up the trace, and a smaller distortion about 20% of the way up (from the bottom). If you're displaying a flat trace, and move it up and down, you'll see the flat line distort at these points.

My guess is that this is probably a sign of something wrong with the CRT deflection plates, though I hope it is something cheaper!

Anyway, Tektronix wants $355 flat rate to repair and calibrate <plus> $750 if it needs a CRT, and I'm wondering if anyone can suggest another repair place that might be a bit more reasonable -- particularly if they can replace the CRT for less. For the money I have in the unit, spending a few hundred dollars is reasonable. Spending a grand is out of the question.

Thanks...

1879. RF amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-09 00:00:00 UTC
From: Gert von Helden <gertvh@sci.kun.nl>
Message-ID: <D8B7tK.GKp@sci.kun.nl>
Source record: 112930

Hi,
I need some advice on how to build, or better where to buy,
an RF amplifier.
We need one in our lab to drive a quadrupole mass spectromere/ion
guide. Nice would be a broadband amplifier that:
1) drives a pure capacitively load (open circuit) of
50 - 500 pF.
2) has a frequency range of 100 kHz to 30 MHz (higher would be
better).
3) accepts input from an external sine wave generator.
4) can put amplitudes of 20 V - 200 V (variable) on the
capacitive load.
5) has two outputs, one 180 deg. out of phase.

The capacitive load are four parallell steel rods, about 3 cm
in diamater, mounted on a circle, one is always out of phase with
the two rods next to it. Tha amplitude and frequency stability is
not terribly important, 1% for amplitudes should be fine.

Can anybody give me advice and/or point me to a company?
For starters, a fixed frequency amp in the 10-30 MHz range
would also be fine.

Any reply, circuit diagrams, lit. refereneces, company names etc.
are greatly appreciated,

Thanks, Gert

: How did you arrive at that value of Q? That is pretty close to the Q of
: the most piston PTFE capacitors I have measured on a HP4191. It is also
: MUCH higher than the Q of coaxial line capacitors or single layer
: transmitting ceramic capacitors. Some loop articles suggest using those
: components!!! If Q is a good apple to apple comparison method and your
: data is correct, a capacitor Q of 600 would cause a 3 dB reduction in
: field strength and doubling of bandwidth.

How does the HP4191 deal with contact losses? One of the problems
with our Hewlett Packard Q meter is that it has these binding posts
for connecting components. Of course, common wisdom is that
pressure fit contacts have high loss compared to soldering or welding.

On the other hand, I'm not about to weld an inductor to our Q meter!

I'm curious as to how you get around this problem. Have you
quantified the losses of the different contact methods?

Source record: 112933

Nathan Sykes (KD4GHG) asked: Does any one know about the "third Method" of SSB generation?

Nathan:

This method is also known as the Weaver method after its inventor. There have been numerous articles over the years about this method. Check old issues of Ham Radio and 73 Magazine circa 1975 to 1980. Those who have used it say it works just fine.

There was also an article in QEX last year about a digital implementation using a Harris IC that uses this method for a digital IF using DSP.

If you do the math (like some of us engineering types do) you will see that there is one slight problem with this method that I have never seen mentioned in any analysis of this method. That is that there is the possibility of distortion due to the frequency aliasing that occurs. Presumably this is not a problem for voice modes since it is very unlikely that you will have substantial frequency components equally spaced from the LO frequency simultaneously. This is an analysis that I have been meaning to perform rigourously for over a decade now. From my initial analysis you would certainly not want to try to transmit music (of more interest to SW broadcasters than amateurs) or other similar signal using this method.

Hi folks,

I'd like to wire up a remote control system that would reliably work within a range of 10-20 meters (~30-60 ft). It must be done using radio, infra-red or ultra-sonic stuff wouldn't work. The controlling is going to be done through tones, like the DTMF system. If it is possible, it'd be cool with a 4-5kHz audio bandwidth, but that's definitely not necessary. The control tones could be transferred with much less.

Size is an important matter. Something like 0.5 x 0.5 inches or even smaller would be an ideal size of the circuit, but it could be larger. Even 1x1" or more. The antenna should not be too long -- the shorter the better.

Power consumption won't be a problem, since it isn't going to be enabled continuously. In fact, it only needs to be powered when it's transmitting, and I think I can handle that.

The receiver can be 1) huge, 2) ugly, and 3) have an extremely long antenna, if necessary.

Since I don't know much about radio technology, I really don't know if such a thing would be possible to do at all. I'm more into digital and analog electronics. If anyone could sort of give me some advice, pointers, ideas or help regarding this project, I'd be very grateful.

Thanks in advance,
-Mathias C. Hjelt

1885. Looking for Component source

Source record: 112936

Hi and thanks for reading this, I'm looking for a couple of I.C.'s for
a project and I'm having trouble finding them. Can anyone help with a
source ? Both are Motorolla I.C.'s

MC13055 an FSK receiver
MC10116 a serial data line receiver

Perhaps someone could tell me the U.K. equivalent or a place to get
these. I'd be most grateful.

I am also looking for a source for a 10 GHz Gunn diode transceiver
module. The actual type seems unimportant providing the Gunn diode
and the Mixer diode are in the same cavity, which should be waveguide
compatible. I have a part number for the suggested device, and a
manufacturer. perhaps you have one or two of these devices in your
junk box that you wouldnt mind selling. (with or without Gunn diode,
I have those)

The device number I have is NEC ND751AAM manufactured by
California Eastern Labs, 3260 Jay Street, Santa Clara. CA 95054.

I would prefer new I.C. 's but a surplus transceiver module.

Thanks in advance

Jim

Boy, I don't know where folks got this. Check the regs, it's there.
1500W pep. Period. 1500 watts average power at the peak of an SSB
signal, or 1500 watts continuous carrier (=1500W PEP). Also 1500W PEP on
an AM signal, meaning a lower carrier power on AM (this makes the AM
boatanchor folks *very* unhappy).

>Ceramics and both sell chip capacitors with Qs in excess of 6000 at HF.

I'm sorry Zak. I was under the impression we were talking about high voltage,
high current variable capacitors for a loop. I didn't know we were talking about multi-layer FIXED chip capacitors! I wonder how high a Q is achievable
in a fixed low voltage vacuum?

>I haven't done the calculations myself, but I've been told that the
>dielectric loss is negligible, and that the loss is due to conductor
>losses. Seems reasonable that adding air cuts losses, since the
>center conductor gets thicker as you decrease the dielectric constant.

Actually it is for both reasons, and that was my point. If you carefully read
my statement you will find I said current was concentrated in a smaller area
of the conductor when the dielectric was added. I listed both of those as reasons PTFE (or any dielectric other than air) increases loss in the type of
capacitor I THOUGHT we were discussing. I plainly said the material adds dielectric losses and increases current density in the conductors (increased
I sqrd R losses), plus it increases undesired series L in many situations. My
point was Teflon is not much better than polyethelyne, but air is much better
than both. Your statement supports that. ;-)

: >In contrast, the (loaded) Q of a 3 ft diameter loop is "only" about

>I like posts with lots of factual data...

I have trouble understanding that comment, the text is garbled. Is that data
out of the same book that said (for years) that common steel wool makes a good HF balun? The data must be "factual" when extracted from a publisher that uses such careful technical editing systems!

Lets not waste anymore space..:-) 73 Tom

1895. Relaxation oscillators

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-09 00:00:00 UTC
From: Jack Mott <jackm@pmafire.inel.gov>
Message-ID: <Pine.HPP.3.91.950509134339.11211A@pmafire.inel.gov>
Source record: 112946

The Maxim MAX038 high frequency waveform generator works from 0 to 20 MHz, and "the basic oscillator is a relaxation type which that operates by alternately charging and discharging a capacitor, Cf, with constant currents, simultaneously a triangle wave and a square wave". The chip can produce "more than two decades of frequency for any value of Cf". [quotes taken from manufacturers data sheet].

I have seen a suggestion from Belgium that the Analog Devices AD9505 programmable pulse edge delay vernier could be used to form an oscillator. This chip has an internal ramp generator and a variable voltage threshold. A variable propagation delay can be set between about 5 ns and 25 ns. Presumably, this device could be set up in a feedback mode to oscillate at frequencies up to 100 MHz.

For a number of reasons, I don't recommend the use of the AD9505 as an oscillator component. I bring it up to show that the basic technology in the MAX032 chip can certainly be extended upwards in frequency.

What are the reasonable frequency limits of relaxation type oscillators? Does anyone have experience with this type of circuit? (Please, don't bring up the 555 timer.)

Not everybody reading this might know the difference between 54 and 74. The 54 series has a much wider temprature range than 74, which makes them far more expensive. Also an F flat pack with a pin spacing of 0.08 inch is more expensive than a J, DIL ceramic with a 0.1 inch pitch.

Or perhaps "YOU guys" (the self-annointed net cops) don't get it.

There are many of us out here who welcome access to ANY and ALL
information relating to our hobby.

"If you don't like it, don't read it."

This seems to be the best suggestion. I would definitely be interested
in subscribing. Such a mailing list should have some provision for a
daily digest as well, since some of us simply cannot receive many
messages daily without attracting adverse attention. (How about another
list called Internet.e-mail.low-profile ....!

This is also a valid point. I'm pretty sure that I would not have access
to such a specialized newsgroup through my present means of access.

: I'm sorry Zak. I was under the impression we were talking about high
: voltage,
: high current variable capacitors for a loop. I didn't know we were talking
: about multi-layer FIXED chip capacitors! I wonder how high a Q is
: achievable
: in a fixed low voltage vacuum?

I was under the impression that people were interested in getting
the maximum efficiency possible out of a loop. Especially techniques
that are easy for homebrewers to try. I think that pointing out
these capacitors is useful--they show that you *can* have a high
dielectric constant *and* a high Q. This is contrary to what you might
expect trying to extrapolate from a coaxial transmission line analogy.

Why the difference?

Look at the transmission line case another way. Usually, the
outer diameter is fixed--we can't make it any bigger. When we add
a dielectric, we normally have to make the center conductor thinner
to keep the impedance constant, another fixed value. But, when we
are building capacitors, we are generally free to keep the conductor
sizes constant.

Tom said his capacitor got hot when he added Teflon, while the
author of the November 1994 QST article on a 100 watt transmitting
capacitor with Teflon said that his didn't. Why the difference?

My guess is that Tom tried to use a bread slicer type capacitor,
with lots of plates welded together. Perhaps this is inferior
in conductivity losses to sliding copper tubes. The nice thing
about the copper tubes is the ease of polishing them to a smooth,
oxide free surface. This is known to make a difference in high
Q circuits. In Tom's case the coupled area was reduced, which must
have increased resistive losses. Doubling losses isn't always a
problem--99 to 98 percent efficiency may be acceptable. On the other
hand, 90 to 80 percent efficiency may be another story... Particularly
when you have compounding effects, such as detuning. In other words,
one problem leads to another--yet another sad tale of woe.

Fortunately, you don't need a sophisticated lab to see for yourself
how well the capacitors work. Just build a loop antenna, run 50 or

100 watts into it, and see if it gets hot! If it does, you need
a better capacitor... If you really want to be scientific, you can
measure antenna bandwidths.

I tried this on sci.electronics but drew no responses- certainly someone here can help with this radio related question. Where can I get REAL information on how modern metal detectors work? I've found schematics for various BFO type detectors but can find nothing but over-simplified explanations of T/R (transmitter/receiver) and PI (pusle induction) systems. I'm also puzzled about "automatic ground cancellation" and "discrimination" circuits. Does anyone know this stuff? The manufacturers are obviosly vague and guarded- a good indication that there is less inside than their price tags would indicate. It's just that the darn stuff works so well...

1909. Designing VFOs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-10 00:00:00 UTC
From: kell@mpac.jsc.nasa.gov
Message-ID: <kell-1005951636580001@netguy.jsc.nasa.gov>
Source record: 112960

I am trying to build a VFO for a SSB transceiver recently published. It was published for 75 meters, and I want to use it on 40 meters, thus the VFO change. The design to be used is that of figure 6-5 in "W1FB's QRTP Notebook". I am starting with a variable cap of from about 10 to 150 pF and trying to design the VFO around it. I have developed some math to help me, I hope there is someone that can tell me if I am on the right track with it. The base is the equation for resonant frequency of f = 1/(2*pi*sqrt(l*c)) whic can be changed to 4*pi*pi*f*f*l*c = 1. Now if one considers a range of frequencies of the VFO of from fmin to fmax caused by changing the variable cap from cmin to cmax (where cmin > cmax - lower c means higner frequency), and break the c into c + cmin and c + cmax you have two equations,

4*pi*pi*fmin*fmin*l*(c+cmin) = 1 and 4*pi*pi*fmax*fmax*l*(c+cmax) = 1.

Setting them equal you get

4*pi*pi*fmin*fmin*l*(c+cmin) = 4*pi*pi*fmax*fmax*l*(c+cmax)

Now divide by 4*pi*pi*l

fmin*fmin*(c+cmin) = fmax*fmax*(c+fmax)

Solve for c and you get

c = (fmin*fmin*cmin - fmax*fmax*cmax)/(fmax*fmax - fmin*fmin)

which should be the remaining amount of capacitance for the circuit. Is this correct?

Once you have c you can find l by l = 1/(4*pi*pi*fmin*fmin*(c+cmin)).

I hope that there is someone out there that can help me. I have the feeling that this is entirely wrong, but can not figure out why. There must be some straightforward way to figure out what the C and L for a VFO based upon a variable cap in hand.

73 and HELP!!

hi, I'm interested if its possible to use a satelite tv receiver(the amstrad srx
350 to reeive the wefax or other weather map transmissions)
Is there a simple interface that one could build to accomplish this.
The satelite receiver tunes in from 700 to 2500 mhz on the other hand the
weather map transmission are on oaround 1640 mhz(i think, or anyways somewhere
in the range of my receiver), what kind of equipment I would need to receive
those signals.(one is analog and the other high definition digital) I asume
one could use the serial port of their computer and some fast software to receive
those images in digital form, does anyone know what the data format is like?
any info wii be greatly appreciated
thanks.

Just about everything about a Yagi affects it to some extent. Larger diameter elements need to be shortened. I can't quote the figures off the top of my head, but for a 3 element beam like you're building, it probably doesn't really matter. For attic installations, 1/8 inch rod for a 2m beam is OK, but if you ever put one up outside, that's very marginal mechanically unless you live in a very benign climate. 3/16 to 1/4 is a good size for 2m beams to be installed outdoors.

Rods instead of tubing should have no effect except for more weight. (Not true at lower frequencies where mechanical considerations become more important. End effects aren't a big concern at 2m. Varying the boom material (conductive vs. non-conductive) definitely affects things. You can use either, but the design needs to take that into account. Method of element mounting is also important with conductive booms. There's insulated element and grounded element, each in through-the-boom or above the boom variants. There's arguments for each method, but since you're reproducing someone else's design, you should use what he used, at least for starters. Then you have a

reference to start experimenting, and learning, from.

Go to the library and look in back issues of QST and Ham Radio for articles on yagis by K1FO and W1JR. W1JR for several years wrote a column in Ham Radio called VHF/UHF world. There's a wealth of information in those columns, about antennas and lots of other things.

Good luck and have fun!

Zak,
I don't know if this is interesting enough to the population to tie up space here. You broached the subject of chip capacitors while I was referring only to changing the dielectric in a given type of capacitor in a given application from air to PTFE. Let me clear that first before I give you measured data on an actual loop antenna.

I don't think your argument is valid because the construction style and material in chip capacitors is very different than variable high power transmitting capacitors. For example, ATC makes some chip capacitors out of K15 Porcelain they call ATC 100 (ref ATC data book). This brew has a dissipation factor of .00007 at 100 MHz, while PTFE has a DF of only .0002 (ref Reference Data for Radio Engnrs). PTFE is 3 times worse than ATC100 material! An ATC design engineer I know feels like PTFE isn't actually that good. He thinks the DF is .0002 at 1 MHz, and gets worse as F increases. But he wasn't positive so he said he would call me back.

The ATC material and chip capacitor construction allows ATC to stack many short wide layers of material fractions of an inch from the terminals. That results in negligible series inductance. The very short conductor path also greatly reduces the resistance in the conductors. All of this adds up to a very good capacitor. The ATC Capacitor Handbook states that "Losses of the capacitor occur primarily in dielectric, the medium for energy storage and transfer". And I'm sure that is the case in small low voltage multi-layer chips. The "Q" they specify is primarily made up of the series resistance of the dielectric, and not the parallel leakage resistance or conductor losses.

OTOH, the PTFE piston capacitor I have evaluated in a loop antenna had a single layer of Teflon separating two in line tubes with a moveable plunger. This system has appreciable distributed inductance (the series resonant frequency was just over 100 MHz, compare that to a 110 pF chip!). BTW series inductance murders the ESR of any capacitor.

These capacitors were manufactured by Polyflon and had an estimated Q of 5000. But when I asked the manufacturer if they ever measured the Q, they said NO. They used your simple method of just using the reciprocal of the DF! So here we have a component with an advertised Q of 5000 that was never measured! The capacitor costs 400 to 700 dollars. I'm really don't care what caused the losses in this cap, the bottom line is it was significantly poorer than specified and estimated. Yet it was very well constructed, and had no moving pressure contacts.

The final design I selected had a nearly square welded plate butterfly capacitor with thick support bars. That provided the shortest and widest current path (lowest series L and R). It was air insulated and had no

pressure contacts carrying RF.

Finally I added PTFE between the plates of this capacitor. That caused a noticeable deterioration in the Q, FS and stability of the test loop. And the ONLY change was the addition of the PTFE and re-tuning the capacitor.

The following were the test results on a 3 foot diameter loop. FS is measured power in a reference antenna located 4.3 wl away. The test antenna and the loop were 50 feet high and horizontally polarized. Test F=10.111 MHz Loop C=110 pF (Xc ~145 ohms). Power was constant from a 50 watt generator through a 10 dB isolation pad, except for frequency stability with long term power application. The stability tests were made with 100 watts and were rated only as good, fair, poor, and unusable.

Home made Butterfly air cap -3dB at 10.103 and 10.119 MHz FS 0 dB (selected as normalized reference) stability good

PTFE Home made butterfly cap (same as above with PTFE) -3 dB at 10.099 and 10.125 MHz FS -1.8 dB stability fair to poor

PTFE piston cap -3dB at 10.097 and 10.125 MHz FS -2dB stability poor

Standard air variable -3 dB at 10.090 and 10.132 MHz FS -6 dB stability fair to good

The tests were only for one antenna and are only comparisons of capacitors. My conclusion is the use of any PTFE (incidentally, the substitution of standard polyethylene resulted in almost identical VSWR BW as the PTFE) degrades the performance of a reasonably well constructed loop. Of course if the loop had more loss, such as one made from coax or small tubing, the difference would be reduced. But if the antenna had less ohmic loss, such as one made from very large diameter copper tubing the difference would increase.

I'm sure you will probably find some small area to find fault with Zak, but these are actual measurements. Are you aware of any other actual measurements, or are they all general estimates?
73 Tom

There are sets of equations, such as that in the ARRL Antenna
book, for figuring out how to compensate for different element
diameters. On the other hand, most people use a computer
modeling program to figure out what effect changes will have on
an antenna. We supply a yagi simulation program for IBM
PC compatibles with the Antenna book. Software is also available
on the net.

: Also, since this antenna will be protected from the weather by
: being mounted in the attic (yeah, homeowner's association), will
: it reduce interference to build the boom and mast out of wood?
: Does this affect the design?

Yes, boom material does affect the design. Usually, it makes it
easier. Conductive booms require adjusting the element lengths
you get on the computer to compensate--wooden booms avoid this
area of study...

Interference and what the boom is made out of are usually unrelated
issues.

Bob Smith (rsmith@internetmci.com) recently wrote
in <3otdq2$bre@news.internetmci.com>:

: I agree, NET COPS find something to do, like maybe try sex - you
: may find that to be more fulfilling than criusing the highway
: handing out citations.

Lets look at this a little differently. This is not a NET COPS issue.

What you are seeing is the local citizens here in these groups trying to clean up the graffitti and posters on all the telephone poles in our neighborhood. The NET COPS can't touch all that graffitti, they are too busy being NET COPS.

I don't think any of us mind a commercial poster with some new information or a new product to sell. You can't ignore it!

Just what does a new cd-rom of amateur programs found here on the internet, have to do with Amateur Space, Policy, Digital, Antennas?

This graffitti should be seen in rec.radio.swap where there is no confusion about the commercial nature of the offer.

Would you like this graffitti problem in your neighborhood? The inner cities look like Hell, because no one cares. These commercial cd-rom folks will stop advertizing in our Amateur Radio Magazines and post here for Free. Do you want all the nuts and bolts magazine ads in our news groups? Hunderds of those little ads every week over and over. Then no more ham magazines...

Almost as bad as the SALE@ALLUS on amateur packet. Does anyone really read all that junk? Oh Sure! go eat a cookie.

Bob ;-)

>John Ackermann AG9V
>john.ackermann@daytonOH.attgis.com

John, see if you can borrow another 'scope. Have a look at the signal
at both deflection plates (with respect to chassis ground). If the signal
looks distorted (which I suspect it will be); then the fault is more likely in
the vertical amplifier which drives the plates. Work your way backwards
towards the 'scope input 'till you see an undistorted signal. The fault
probably lies somewhere near there. Fortunately, Tek use sockets for their
active devices, so removal for checking and substitution is easy. My bet is
you have a crook transistor, op-amp, or resistor gone high. Remember to check
your power supply rail voltages too.

I'd suggest calling Fair Radio Sales in Lima, Ohio.
I bought a throat mic from there years ago. The fidelity was fairly poor,
depending on how you placed it on your larnyx...

Not uncommon from what I understand...

Also, just about all the common garden variety word processing program can handle HPGL for input as a graphics frame (e. g. wordperfect, etc.), but some you might have to print out to get a real readable picture given some screen resolutions.

there are several IEEE-488 cards and control software on the market. from there, it's your problem to string together the commands to send and the responses to look for to build your program.

quite possible there might be some graphics display tools in some of them but i'll bet you have to save to file first and then import into a WP system of some kind...or get one of those printers (like a QMS 860) that "knows" different data streams and reacts accordingly...then you can just dump your job to the printer.

for the laserjet II there was a thing called 'Plotter in a Cartridge" by Pacific Data Products, i think. you'd start up the printer with this installed, and then send a command string to the printer to turn it into a plotter and then follow with plot commands...emulated a 7475A i think with A size paper....it's been a long long while since we used one of those at work...

1922. 2m parametric amp/message for K4MSG.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-11 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995May11.113013.37373@ucl.ac.uk>
Source record: 112973

I posted an artical about 2m parametric amps here. Paul, k4MSG replied he had a circuit from an old ARRL VHF manual and would be willing to copy it if I wanted. I would indeed like a copy, but my attempts to reply to his e-mail have failed, since my unix system does not appear to know about his e-mail address.

If he sees this, could he plase sent me the artical. Sorry I cant reply personally.

1923. Re: Designing VFOs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-11 00:00:00 UTC
From: tayloe_d@sat.mot.com
Message-ID: <1995May11.195428.5694@schbbs.mot.com>
Source record: 112974

>I am trying to build a VFO for a SSB transceiver recently published. It
>was published for 75 meters, and I want to use it on 40 meters, thus the
>VFO change. The design to be used is that of figure 6-5 in "W1FB's QRTP
>Notebook". I am starting with a variable cap of from about 10 to 150 pF
>and trying to design the VFO around it. I have developed some math to
>help me, I hope there is someone that can tell me if I am on the right
>track with it.

The basic equation is f = 1/(2*pi*sqrt(L*C))

Reworked in other useful ways:

L = 1/(2*2*pi*pi*f*f*C)
C = 1/(2*2*pi*pi*f*f*L)

Pick an L: 24 Turns on a T-50-2 toroid core is about 2.3 uH. (recheck the equation for toroid inductance in the ARRL Handbook)

For a high frequency of 7.35 Mhz, we need a C of:

1/(4*9.87*7.35e6*7.35e6*2.3e-6) = 2.038e-10 or 204 pf

For the low frequency of 7.150, we need a C of:

1/(4*9.87*7.15e6*7.15e6*2.3e-6) = 2.154e-10 or 215 pf

Therefore, you need a varible cap with about a 9 to 10 pf tuning range, but you have a 10 to 150 pf varible. No problem!

Use a small series cap to reduce your effective tuning range to a 10 pf range, and use a fixed cap for the rest.

For two capacitors in series, the equivelent C is:

C = 1/(1/C1 + 1/C2)

Pick 30pf as an initial guess:

If the varible is at 150 pf you have: 1/(1/150 + 1/30) or 25 pf.
If the varible is at 10 pf you have: 1/(1/10 + 1/30) or 7.5 pf
The range is 25-7.5 or 17.5 pf which is too big, so pick a smaller C

Pick 20pf as the series cap:

at 150 pf, get 1/(1/150 + 1/20) or 17.6 pf
at 10 pf, get 1/(1/10 + 1/20) or 6.6 pf

Total range is 17.6 - 6.6 or 11 pf.

This may be close enough for you or you can try a bit smaller C and try again.

Since you need 204 pf at the high end, and we have found a combination that yields 6.6 to 17.6 when 20 pf is in series with your varible cap, your need C is a fixed 204-6.6 or 197.4 pf C in parrellel with the series combination of 20 pf and your variable capacitor.

The 197.4 pf is probably really 180 pf plus a trimmer cap.

There will of course be stray C in the circuit.

Use NPO type caps or polystyrene (sp?) for stability.

Everything should be mechanically stable or it will "ring" when the VFO is "pinged" mechanically.

The next step will probably be querries about VFO drift!

Good Luck!

- Dan Tayloe, WB0NVB, Phoenix, Az.

People who have to use throat mics a lot, like the military, don't
like them very much. They give very poor speech quality and can be
very uncomfortable. You really need to press them against the larynx
for them to work properly, which is a nuisance. You could probably
pick some army surplus ones up at an amateur radio rally (hamfest
in the US).

Try Faulkner Enterprises of America (312 River St, Sabula IA; (319) 687-2479)
This company sets up at many of the hamfests around here. They deal in
surplus, however most are unused and some less than 1 year old, they take care
of the stock and charge them periodically. I don't know if that qualifies as
NEW but it's pretty damn close. They offer a guarantee, I forget the exact
details. I've bought several units from them at hamfests without any problem.
Price is about 1/4 the cost of "new" ones from Digi-Key, etc. Of course, if
you have a continuing need for exactly a certain type, etc, then you may need
to go to a factory distributor.

: If so, can anyone give me pointers on how to accomplish this..

Yes, PIN diodes can do just fine there. In fact, there has been quite a bit of surplus hardware from the Japanese Personal Radio Band, 903-905 MHz, which does this. Mitsubishi, Toshiba and others make not only PA modules in the 1 mw -> 10W territory but also companion PIN switch modules.

I use some of this hardware in the 904 MHz digital radios I built. I have been able to switch 10+ watts with .5 dB or less insertion loss on transmit and not much more on receive and achieve turnaround times of under 40 microseconds. In fact the switch itself appears to be much faster than this.

Mitsubishi, at least, builds PIN switches for other bands. They indicate 2M, 70 cm, 33 cm and 27 cm versions in their catalog and I've seen and used all but the 2M one (model number MD007, I believe).

Generally, the T/R switches appear to be one or two quarter wave lines with a shunt diode(s) in the receive path and a single series diode in the Tx path. The 1296 MHz versions handles 30 watts just fine. It works well with the M57762 PA module.

If you are looking for one or two PIN switches to try for a ham project, I think I can find some that are surplus to my needs.

To do this is pretty much impossible; the RF section for 49 MHz is utterly unlike the stuff used at the higher frequencies, which is why the higher frequency units cost so much. You don't get something for nothing.

However, you _can_ easy convert the RF section up to the 6 meter amateur radio band, add a PTT switch for simplex, and have yourself a nice little very-low-power 6M HT. I added a 2N2222 output stage on mine and boosted the power up to almost 200 mW, which is enough for me to regularly talk to friends across town, and sometimes do a bit of DXing in good conditions.

There are reports that some of the cellphones which use the Motorola chipset can be cranked up to the 2M band, but that the performance at the higher frequency is very poor. Still, it's the only HT that you can get at a garage sale for five bucks, and if you can hear the local repeater and manage to key it up, you're home free.

Message-ID: <1995May11.004355.8149@wb3ffv.ampr.org>
Source record: 112984

The short answer is that there is no standardized color code for ferrite or powdered iron cores. Please read my letter in the March 1994 issue of QST, on page 81, in the Technical Correspondence section, titled "Toroidal-Core Color Codes". If you do not positively know who made a particular core, its color tells you nothing whatsoever and cannot be trusted. Most ham projects seem to use the powdered iron cores sold by Amidon (and made by Micrometals), and those are color coded. They have become a sort of standard in homebrewing, and make it appear that there is a standard color code, but it is only one manufacturers color code system. On the other hand, since we do seem to stick pretty much with a single supplier, we can specify cores of a certain color with a fair amount of safety. (But it's usually best to keep on walking when you see bins of cores at a hamfest--you have no idea who made them, and it's risky at best to trust the colors on them.) 73 de WA8MCQ

>boatanchor folks *very* unhappy).

I know where they got it. PEP is the peak RMS power. The other power used is the short term AVERAGE RMS power. They get confused and think the AVERAGE RMS power is just the RMS power, and the PEP is just the peak power and not the peak RMS power. On CW of course the short term average RMS power is exactly equal to the PEP power, but somehow that is confusing.

And it is very common.

W8JI Tom (w8jitom@aol.com) wrote:
: Zak,
: I don't know if this is interesting enough to the population to tie up
: space here. You broached the subject of chip capacitors while I was
: referring only to changing the dielectric in a given type of capacitor in
: a given application from air to PTFE. Let me clear that first before I
: give you measured data on an actual loop antenna.

Why not? Do you know there are actually people who want yet another
newsgroup, in hopes of getting more posts on topics like this.

: I don't think your argument is valid because the construction style and
: material in chip capacitors is very different than variable high power
: transmitting capacitors. For example, ATC makes some chip capacitors out
: of K15 Porcelain they call ATC 100 (ref ATC data book). This brew has a

: The ATC material and chip capacitor construction allows ATC to stack many
: short wide layers of material fractions of an inch from the terminals.
: That results in negligible series inductance. The very short conductor
: path also greatly reduces the resistance in the conductors. All of this
: adds up to a very good capacitor. The ATC Capacitor Handbook states that

Perhaps such ideas ought to be considered when designing capacitors
for transmitting loop antennas.

: OTOH, the PTFE piston capacitor I have evaluated in a loop antenna had a
: single layer of Teflon separating two in line tubes with a moveable
: plunger. This system has appreciable distributed inductance (the series
: resonant frequency was just over 100 MHz, compare that to a 110 pF chip!).
: BTW series inductance murders the ESR of any capacitor.

: These capacitors were manufactured by Polyflon and had an estimated Q of
: 5000. But when I asked the manufacturer if they ever measured the Q, they
: said NO. They used your simple method of just using the reciprocal of the
: DF! So here we have a component with an advertised Q of 5000 that was
: never measured! The capacitor costs 400 to 700 dollars. I'm really don't
: care what caused the losses in this cap, the bottom line is it was
: significantly poorer than specified and estimated. Yet it was very well
: constructed, and had no moving pressure contacts.

I know the Q of the ATC chip capacitors is rather good--see the December
1991 QST p.33 for a very narrow bandwidth LC filter using them (8 kHz at
3.8 MHz).

Sounds like that manufacturer was in error, just like those
manufacturers who build preamps and pass along the noise figures
claimed by the semiconductor manufacturers without ever measuring

the noise figure. On the other hand, the loss tangent or dissipation
factor is a real useful number to know--it gives you a clue into
what can be achieved.

I have to admit, I like to know why numbers don't match up.
For instance, I figured out that semiconductor manufacturers
have to use (relatively) high loss tuners and somehow factor that
error out of their NF numbers. Thus, 0.4 dB NF and an optimum
reflection coefficient of 0.9 may not be terribly accurate; your
best bet is to pop a few devices in a low loss cavity fixture and
see what happens...

much useful test data deleted

: The tests were only for one antenna and are only comparisons of
: capacitors. My conclusion is the use of any PTFE (incidentally, the
: substitution of standard polyethylene resulted in almost identical VSWR BW
: as the PTFE) degrades the performance of a reasonably well constructed
: loop. Of course if the loop had more loss, such as one made from coax or
: small tubing, the difference would be reduced. But if the antenna had less
: ohmic loss, such as one made from very large diameter copper tubing the
: difference would increase.

Another way of reducing loss is to reduce the loaded Q of the
system. The PTFE capacitors you didn't like might well be
acceptable in a different design, such as a loop for 10 meters
(Novice/Tech voice operation).

One of the problems with RF system design is that "high loss" or
"too lossy" really doesn't mean anything. That filter I mentioned
had 21 dB of loss, but worked great. I could hear QRPers despite
the 3 watts coming down the feedline only 22 kHz away from where
I was listening... On the other hand, 0.02 dB of loss can make
difference in the Microwave Update NF contest (I just compete,
I don't write the rules.)

Trouble is that would degrade the noise figure of your front end by 8dB. Since a noise figure of 2dB is about what you want on 2m, you receiver would be very deaf. A better bet would be a less selective, but lower loss filter.

If anyone out there has a program that can help wind coils please tell me where I can get it. I have a program like that, but the danged thing is old and i have no docs; no info as to who wrote it and it dont work. Locks up my machine. All I have is an .exe file called coil.exe. It would sure be neat to have, The info screen says that all i need is the wire diameter and the inductance value wanted and it will tell me how big and how many turns, sure would be handy.
thanks

Any help on converting a motorola mitrek, syntor x, GE (dont remember the model #) would be appreciated. They all have eproms for frequency. Got a programmer but dont know how to enter correct data. I'm sure that somewhere out there is a FAQ for this, but I dont know where it is located, Can someone help me please? ANY info would be appreciated. These are neat radios and I got them very, very cheap. They also work good. They are VHF hi band radios.
frequencies are in the 150-160 range, I know that it can be done pretty easy. I have a pretty good knowledge of radios and have plenty of test equipment to work with. Thanks.

Since we're getting off on a tangent here, let's step back and take a look. Even though netiquette frowns on advertising, I enjoy hearing of new products that are closely related to amateur radio. Let's face it...for those of us with 'Net access, we're going to hear about it here well before it hits CQ, QST or the other mags.

Here's something that works for the Linux enthuiasts: a moderated group for announcements, which permits new product announcements, as well as other announcements of general interest to that group. The subject lines for advertising-related announcements begin with "COMMERCIAL:" While I ordinarily dissaprove of moderated groups on censorship grounds, this works quite well. Linux enthusiasts can browse this newsgroup, skipping all posts that are clearly marked as commercials if they wish. The function of the moderator is to keep posts not related to Linux off the newsgroup.

So...I'll pose the question...are we ready to propose adding rec.radio.amateur.announce to the hierarchy?

Thanks guys...

This NET-COP phenomena is the damnedest counter-productive thing I have ever seen. If I was truly spamming the groups with some trash, I would love every netcop that jumped on my posting. Hey, in advertising, any press is good press. Let's say I only intended to post just once but I made a mistake and it took a couple of postings to correct that. I would have only created three postings about as long as this one is. If that was all, I would be worried about getting enough exposure. BUT NOOO... I can count on at least a half dozen jerks with their heads up their butts jumping on my case and keeping my ad running for at least a couple of weeks. It doesn't even matter whether or not my "ad" is relevant to the newsgroups I post it in. I certainly welcome the quarterly, less than 1k, posting about the Ham CD's. Even if I hated them, would I want to have the newsgroup cluttered with 100k of netcop ranting? A good cop understands some human nature and knows when to let things slide or when to just let go...

We have a similar group now. rec.radio.amateur.info

How about rec.radio.marketplace for new product announcements

Many of the other large collections of newsgroups have established the
marketplace group for similar posts. It has been proved quite popular
with readers, as well as the marketers. One stop shopping.

Message-ID: <9504128002.AA800296261@mails.imed.com>
Source record: 113001

I didn't save the info on the original posting.

I have some experience with some VERY old Tek scopes that work exactly as you describe and they are not broken. These are very old 5 inch round crts. The graticle on these old scopes only covered about 1/3 of the total area of the screen. If you tried to move the trace beyond the graticle, the beam hit one of the deflection plates!

If these don't describe your scope, then it is broken. If it is broken, you might also look at the accelerator voltage. If it is too low, the beam could very easily hit the vertical deflection plates. The previous suggestion to borrow another scope to troubleshoot yours is a good idea.

>>RMS power is exactly equal to the PEP power, but somehow that is
>>confusing.

Okay, then why does my "peak" reading Coaxial Dynamics wattmeter
read 1500 PEP on CW, but something less (1400W) with a dead-full
carrier? Is it due to a different plate impedance at the final
amplifier stage? Or just a measurement inaccuracy?

Does anyone know how to change the *time constant* of the peak reading
mod kits for both Bird & CD meters. The time constant is too large
and its tough to tweak for max smoke while speaking. The el-cheapo
($100) Diamond meter I had worked well for tuning while talking.
Quick band changes are a must when operating a contest. Just curious.

You can bet the ranch it is because you have envelope distortion or modulation caused by poor power regulation in the radio or amplifier. Most of it is probably power supply sag in the amplifier. You almost certainly have more power when the key is first closed than after a second or so.

1953. coherent cw

Funny you mentioned this, Joanne. I wanted to build an almost identical design for years, starting in the mid-70's. It was the complexity (and potential cost) of the project that stopped me. Do you know of any commercial receivers or transceivers that use this approach?

Again I have experienced the problem of attempting to answer a request for information, this time to the sender of the above message, with the product of my effort bouncing back. What is wrong? It happens often and makes me feel like not bothering anymore. Do all these users have no "mailbox" for receiving incoming stuff; do they just send out a message and disappear? I tend not to believe in filling up the postings with material hardly of interest to more than one reader, so email seems like the solution for special needs, like the above, leaving only the general interest information over for posting to the group. Getting 30% of the email back kills any sense of doing something useful-there are better things to do with the time! Can one identify these lost causes in advance?

1956. Info on 4-400A transmitting tube

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-12 00:00:00 UTC
From: "Jake A. Hellbach" <Jake_A._Hellbach@ccmail.mobil.com>
Message-ID: <3ovnef$39u@dlsn31.dal.mobil.com>
Source record: 113007

I bought a used 4-400A tube at a ham fest thinking I already had
a schematic to build an HF amp using it, but in looking I found I
didn't have anything on it (just the specs. on the tube from an old
ARRL manual). I have schematics on the 3-500 as well as others
and I was wondering if the schematic would be very different for
the 400.
Or does anyone have a something for this tube? I would pay for copying
and postage.
Also how do you tell which is pin 1? I've never used these types of
tubes.

Thanks for any info.

PLEASE LISTEN BEFORE YOU START FLAMING ME. I THOUGHT THESE
THINGS WERE SCAMS ALSO BUT IN THE LAST WEEK I RECEIVED
$50,000 IN THE MAIL FROM PEOPLE AROUND THE WORLD. I DON'T
KNOW ABOUT PYRAMID SCHEMES OR ANYTHING LIKE THAT BUT I DO
KNOW I MADE $50,000 AND ALL I GAVE WAS 5 MEASLY BUCKS. I WANT
OTHER PEOPLE TO JOIN IN MY GOOD FORTUNE!!!
-A satisfied customer!

INSTRUCTIONS

Follow these instructions EXACTLY, and in 20 to 60 days you will
have received over 50,000.00 dollars IN CASH.

[1] Immediately mail $1.00 to the first 5 names listed below,
starting at number 1 through number 5. SEND CASH ONLY. (Total
investment: $5.00 + postage) >ENCLOSE A LETTER WITH A NOTE
SAYING:
"Please add my name to your mailing list". Include your name
and mailing address. This is a legitimate service that you are
requesting and you are paying $1.00 for this service.

[2] Remove the name that appears as number 1 on the list. Move the other 9 names up one position (Number 2 becomes number 1, number 3 becomes number 2, and so on). Place your name, address, and zip code in the number 10 position.

[3] With your name in the number 10 position, upload this ENTIRE file to 15 (Fifteen) different bulletin boards (local or out-of-state). You may post it to the BBS's message base or to the file section. Name it FASTCASH.TXT, and use the file description comments to draw attention to this file and its great potential for all of us.

[4] Within 60 days you will receive over $50,000.00 in CASH. Keep a copy of this file for yourself so that you can use it again and again whenever you need money. As soon as yu mail out these letters you are automatically in the mail order business. People will be sending YOU $1.00 to be placed on your mailing list. This list can then be rented to a broker that can be found in your local yellow pages listings for additional income on a regular basis.

The list will become more valuable as it grows in size.
This is a service. ** IT IS PERFECTLY LEGAL **
If you have any doubts as to the legality of this service, please refer to Title 18,h sections 1302 and 1341 of the Postal Lottery Laws.
NOTE: Make sure that you retain EVERY name and address sent to you, either on computer or hard copy, but do not discard the names and notes that people send to you. This is PROOF that you are truly providing a service, and should the I.R.S. or some other government agency question you, you can provide them with this proof!
Remember, as each post is downloaded and the instructions carefully followed, five members will be reimbursed for their participation as List Developer with $1.00 each. Your name will move up the list geometrically so that when your name reaches the number 5 position you will be receiving thousands of dollars in cash.
REMEMBER - THIS PROGRAM FAILS ONLY IF YOU ARE NOT HONEST -PLEASE!!PLEASE BE HONORABLE...IT DOES WORK! THANK YOU.

1. Jason Song 50 La Verne Ave. Long Beach CA 90803
2. Hardeep Malik 6475 Marguerite St. Vancouver BC V6M 3L5 Canada
3. Chris Kraemer 450 Beacon St Boston MA 02115
4. John Onysko 3790 Biltz Road Kent OH 44240
5. Dien Tran 19 Presnell St. Portland ME 04102
6. Marc Provencher 444 Capisic St. Portland ME 04102
7. James Grubic P.O. Box 8161 Bozeman MT 59773
8. Zach Nelson 311 Sycamore Road West Reading PA 19611
9. Francis Pineda 11402 Grago Dr. Fort Washinton MD 20744
10. Richard Maiers 400 W. College Ave Las Cruces NM 88005

The following letter was written by a participating member in this program.

****

To those with the COMMON sense to participate in this easy money opportunity:

About six months ago I received the enclosed post in letter form. I ignored it. I received about five more of the same letter within the next two week. I ignored them also. Of course, I was tempted to follow through and dreamed of making thousands, but I was convinced it was just another gimmick and could not possibly work.

I was wrong! About three weeks later I saw this same letter posted on a local bulletin board in Montreal. I liked the idea of giving it a try with my computer. I didn't expect much because I figured, if other people were as skeptical as I, they would not be too quick to part with $5.00. But, I BUY LOTTERY TICKETS WEEKLY IN MY PROVINCE AND HAVE NOTHING TOO SHOW FOR IT BUT TICKET STUBS! This week I decided to look at this as my weekly lottery purchase. I addressed the envelopes and mailed out $1.00 in each as directed. Two weeks went by and I didn't receive anything in the mail. The fourth week rolled around and I couldn't believe what happened! I can not say that I received $50,000.00, but it was definitely well over $35,000.00! For the first time in 10 years I got out of debt. It was great. Of course, it did not take me long to go through my earnings, so I am using this excellent money making opportunity once again.

FOLLOW THE INSTRUCTIONS AND GET READY TO ENJOY!

Please send a copy of this letter along with the enclosed letter so together we can convince people who are skeptical that this really does work!

Good Luck,

Charles Kust

P.S. Everyone participating in this program keeps track of all the names from whom they receive money. If you decide NOT to be HONEST, and NOT to send money to the first 5 people on the list, you can always be tracked down and sued, and I'm sure that you DON'T want that.

Well, in any case, we hope that you follow through with all the instructions in this letter in order to keep this thing going. If you do, you may expect to start getting mail from your first clients in less than three weeks.

Good luck, and we hope that you can benefit from this, just like numerous others from coast to coast, and all over the world.

>and its tough to tweak for max smoke while speaking. The el-cheapo

On the Bird, the peak ckt is potted, but I repaired a broken one by chipping
all the potting compound off the board. There is a capacitor C1 and a resistor
R7 (that's what they are called in my notes, I think they were labeled on the
board) which is the time constant. Paralleling R7 with another resistor will
speed up the decay. The chip is just a 4 opamp IC like an LM324. The resistor
cap combination are connected between pin12 and gnd. The last amp, pin12 in and
pin 14 out, is a follower so as not to load the time constant capacitor. I thinkthe ckt. is
dumb because they use 2 batteries which last 24 hours if you forget to turn it off. I use a
ckt with a single ended opamp LM358. You can buy the kitfor it from KF8AT. Works on any
meter. Use 2 for crossneedle meters and set the
timeconstant long to see your SWR while you talk. Install a switch and have fastor slow
timeconstant.
KF8AT, Floyd is at 810-391-6660. He is also the Collins Net manager.

When I look through the Digi-Key catalog for crystals, some are described as having a load capacitance (15-30 pf) and others are described as "series". What is the difference? Also, the PIC microcontrollers have fuse bits to distinguish between three types of crystals: LP, XT, and HS. Would anyone know if this is standard nomenclature? Finally, I would be curious to know what an AT cut crystal is.

>And it is very common.

RMS voltage and RMS current are useful ways to describe AC signals.
A 100 V RMS voltage will heat a resistive load with same power as 100 V DC
voltage does. That is the definition.

RMS power can be calculated but it has no meaning. 100 V RMS voltage
at 100 ohms resistive load will heat the load with 100 W _average_ power.

Finnish amater radio regulations explain the PEP and carrier power
concepts quite well (IMHO):

---------- Quote on

1.10 The power of the radio station is defined as follows:

1.11 Peak Envelope Power (pX) (of a radio transmitter): The
average power supplied to the antenna transmission line by a transmitter
during one radio frequency cycle at the crest of the modulation
envelope taken under normal operating conditions (RR 151).

1.12 Mean power (pY) (of a radio transmitter): The average
power supplied to the antenna transmission line by a transmitter
during an interval of time sufficiently long compared with the
lowest frequency encountered in the modulation taken under normal
operating conditions (RR 152).

1.13 Carrier Power (pZ) (of a radio transmitter): The average
power supplied to the antenna transmission line by a transmitter
during one radio frequency cycle taken under the condition of
no modulation (RR 153).

---------- Quote off

(See "Finnish Amateur Radio Assosiation" home page at
http://www.compart.fi/SRAL/Welcome.html
for more information)

The (RR xxx) tags point to international Radio Regulations.

Please note that _both_ the carrier power and PEP power definitions contain the word average. That is the way AC power is defined!

For instance 100 W CW or 100 W FM signal is 100 W PEP.

Indeed, the 4-400A is *quite* different from a 3-500, not the least
of the difference is that it is a tetrode rather than a triode.
Trying to use one in the typical grounded-grid configuration used
with the 3-500 will be futile. Most uses of the 4-400A are in common
cathode configuration, and the gain is quite high in that configuration.
Stability can become a serious issue if you aren't careful. The high
power gain, however, means that the 4-400 is suitable for boosting
low power equipment to quite high power levels. Since the FCC put
an external amplifier power gain limit on commercial amplifiers sold
to amateurs, you don't see many commerical examples of the common cathode
circuit anymore. Try one of the older editions of the ARRL Handbook.

Note, these are *carbon* microphones. You'll need a local battery
circuit to interface them with modern radios. Fidelity sucks too.
For a modern throat microphone, you want a piezo pressure zone
design. These require an interface circuit too, but fidelity will
be better. You'll probably do better to consider an *ear* mike.
These work by sound conduction too, and are commercially available
to match modern radios.

>Ted Kell@mpac.jsc.nasa.gov
>KC5CUW/AA

Ump, I'm too tired to follow your math at the moment. But the whole problem is fairly simple. For a given L and F the capacitance to resonate is
1) C = 1/((2*pi*F)^2*L

Presume a fixed L and a variable C. Then the C to resonate with a given frequency varies with 1/(F)^2. If you have C1 at F1 and C2 at F2 you get the obvious relationship:

2) C1/C2 = (F2/F1)^2

Or alternatively:
3) C1 = (F2/F1)^2 * C2

Then you can get the difference between C1 and C2 as
4) C2-C1 = C2 (1 - (F2/F1)^2))

Since you know C2-C1 is ~140pF you can plug that and the frequncies into 4 and get C2. Then from 3 you can get C1. From this you can calculate the shunt capacitance you need by subtracting the 10pF minimum capacitance from C1. And from 1) and C1 you can calculate L.

Best give L and Cshunt a modest amount of trimming range so that you can calibrate the puppy if you want to.

Jack-
Quartz crystals can be compared with series and parallel LC tuned circuits. They have both a parallel (high impedance) resonance and a series (low impedance) resonance, at slightly different frequencies. The series resonant frequency can be affected by a series reactive element, like an inductor. Frequency is normally specified with no series reactance.
The parallel resonant frequency is affected by a parallel reactance, usually a capacitance. Thus, a "load" capacitance must be specified when ordering.
Radio crystals are cut from natural quartz crystals. It is found that crystals cut at differing angles from the natural quartz axis, have differing frequency-versus-temperature characteristics. An "AT" cut crystal has the most stable temperature characteristic.

Would anyone know if this is standard nomenclature? Finally, I would be curious to know what an AT cut crystal is.<

Jack:
When a crystal is specified with a load capacitance, it is calibrated for "parallel" (anti) resonance. The crystal isn't really operated at its own parallel resonant frequency but at a frequency where it appears to be an inductor that resonates with the parallel combination of its own shunt capacitance and that of the load capacitor. A series mode crystal doesn't have a specified load capacitance. There is no physical difference between the two, the only difference is the calibrated frequency.

LP, XT, and HS. don't mean anything to me. I'm sure someone else can help with this. An AT cut describes the way the crystal lattice was oriented when the slice was taken. Different cuts (AT, BT, SC, etc) have various properties having to do with temperature stability, drive levels, etc.

Jack Mott <jackm@pmafire.inel.gov> wrote:
>When I look through the Digi-Key catalog for crystals, <snip>

Hi Charles,

I have no info regarding LP, XT or HS crystals, but the following should help to answer some of your other questions. All excerpts are from "The Radio Handbook", Eleventh Edition, Copyright 1947 by Editors and Engineers, Ltd.

73, Jack WB3U

The shunt capacitance of the electrodes and associated wiring (crystal holder and socket, plus circuit wiring) is represented by the dotted portion of Figure 4B. <Figure 4B shows a dotted-line capacitor, C2, labeled "Stray Shunt" connected in parallel across an inductor and capacitor which are in series> In a high frequency crystal, this will be considerably greater than the capacitive component of an equivalent L/C circuit, and unless the shunt capacitance is balanced out in a bridge circuit, the crystal will exhibit both resonant (series resonant) and anti-resonant (parallel resonant) frequencies, the latter being slightly higher than the series resonant frequency and approaching it as C2 is increased.

The parallel resonant characteristic permits the crystal to be used in place of an L/C tank in an oscillator, with greatly increased stability as a result of the much higher Q.

The series resonance characteristic is employed in crystal filter circuits in receivers . . . and also in certain oscillator circuits wherein the crystal is used as a selective feedback element in such a manner that the phase of the feedback is correct and the amplitude adequate only at or very close to the series resonant frequency of the crystal . . .

The crystal "blank" is cut from the raw quartz at a predetermined orientation with respect to the optical and electrical axes, the orientation determining the activity, temperature coefficient, thickness coefficient, and other characteristics. Various orientations or "cuts" having useful characteristics are illustrated in Figure 5. <Figure 5 contains several sub-drawings too complex to describe well in print.> . . .

The temperature coefficient of frequency for various crystal cuts of the "-T" rotated family is indicated in Figure 5.

<<<
The following table showing angles of cut is part of Figure 5:

High Frequency AT,BT
Low Frequency CT,DT,ET,FT

AT +35 deg, 15 min
BT -49 deg
CT +38 deg
DT -52 deg
ET +66 deg
FT -57 deg
>>>

These angles are typical, but crystals of a certain cut will vary slightly. By controlling the orientation and dimensioning, the "turning point" (point of zero temperature coefficient) for a BT cut plate may be made either lower or higher than the 75 degrees shown. <This number refers to another aspect of the cut angle> Also, by careful control of axes and dimensions, it is possible to get AT cut crystals with a very flat temperature-frequency characteristic . . .

For frequencies between 500 kc. and about 6 Mc., the AT cut crystal now is the most widely used. It is active, can be made free from spurious responses, and has an excellent temperature characteristic. However, above 6 Mc. it becomes quite thin, and a difficult production job. Between 6 Mc. and about 12 Mc., the BT cut plate is widely used. It also works well between 500 kc. and 6 Mc., but the AT cut is more desirable when a high order of stability is desired and no crystal oven is employed . . .

By grinding the crystal especially for harmonic operation, it is possible to enhance its operation as a harmonic resonator, and BT and AT cut crystals designed for optimum operation on the 3rd, 5th, and even the 7th harmonic are available. The 5th and 7th harmonic types, especially the latter, require special holder and oscillator circuit precautions for satisfactory operation, but the 3rd harmonic type needs little more consideration than a regular fundamental type. A crystal ground for optimum operation on a particular harmonic may or may not be a good oscillator on a different harmonic or on the fundamental. One interesting characteristic of a harmonic cut crystal is that its harmonic frequency is not quite an exact multiple of its fundamental, though the disparity is very small.

The harmonic frequency for which the crystal was designed is the "working frequency". It is not the "fundamental", but the crystal itself actually oscillates on this "working frequency" when it is functioning in the proper manner.

You may want to take a look at "A DSP Version of Coherent-CW," by Bill DeCarle, VE2IQ. It's in the February 1994 issue of QEX (contact ARRL for reprints: lweinberg@arrl.org). It uses an IBM PC and a small circuit board that appeared in the January 1992 QST and also in recent Handbooks ("A Receiver Spectral Display using DSP").

Hi,

Changing a rig's frequency is more difficult the more the two frequencies
differ. E.g. changing PMR equipment from 155 MHz to 145 MHz is feasible,
while changing the same equipment to 430 MHz is a major undertaking
(you are probably better off building new stuff in the last case).

The difference in techniques applied in equipment for 46 MHz
and 900 MHz is very significant.
For this readin, I think that it is practically impossible
what you want. You are better off building dedicated 900 MHz stuff
from scratch.

It is much easier to change a 46 MHz phone to 52 MHz. You would probably have to have the crystals custom-made for your operating frequency, but most of the newer phones use 2 frequencies in the 46-49 MHz range, and these can be used with very little modification on 6 meters.

The older phones used 2 MHz from the base to the handset (house wiring was the antenna) and 46 MHz from the handset to the base. Maybe these could be used cross-band 160 to 6 meters? :-)

I did see a new phone that operated in the 900-MHz range, it was perhaps a Panasonic. (I forget.) The circuit looked rather complex to try to modify to the amateur bands, but I imagine it would be possible. It did have some sort of DSP for noise reduction. This was a household cordless, NOT a cellular.

>Ted Kell@mpac.jsc.nasa.gov
>KC5CUW/AA

Ump, I'm too tired to follow your math at the moment. But the whole problem is fairly simple. For a given L and F the capacitance to resonate is
1) C = 1/((2*pi*F)^2*L

Presume a fixed L and a variable C. Then the C to resonate with a given frequency varies with 1/(F)^2. If you have C1 at F1 and C2 at F2 you get the obvious relationship:

2) C1/C2 = (F2/F1)^2

Or alternatively:
3) C1 = (F2/F1)^2 * C2

Then you can get the difference between C1 and C2 as
4) C2-C1 = C2 (1 - (F2/F1)^2))

Since you know C2-C1 is ~140pF you can plug that and the frequncies into 4 and get C2. Then from 3 you can get C1. From this you can calculate the shunt capacitance you need by subtracting the 10pF minimum capacitance from C1. And from 1) and C1 you can calculate L.

Best give L and Cshunt a modest amount of trimming range so that you can calibrate the puppy if you want to.

You're on BITNET, and you complain? :-)

I've found that bounces are a fact of life with sites that have aol.com
in their path. And the user is on Prodigy, which is another sore spot.
BITNET sites aren't a lot better. The internet isn't as inter-net as
we'd like at times. The interface between the various subnets doesn't
always have well maintained routing.

Jackson here in the UK still make them, as they are listed in the Maplin
catalogue. They are *rather* expensive; about 10 pounds for a single gang
365 pF. Maplin Electronics are on (01702) 554161, here in the UK.

>acceptable in a different design, such as a loop for 10 meters
>(Novice/Tech voice operation).

Zak,
Well, now you've hit on a common problem. It always is a function of Rloss over Rrad in an antenna. Look at mobile antennas too. My truck's ground loss resistance is 17 ohms on 160. What good would it do to keep the coil resistance below 8 or 10 ohms? The ground loss dominates.

The same goes for the loop. Making the loop larger in area increases the efficiency FOUR times every time the loop AREA doubles. That is only if R loss stays the same, so if I use a poor capacitor but a very good material to build the loop itself, I will see most of that improvement. Why don't articles explain the pro's and con's more, instead of a Xerox formula? Then people would know how it works. 73 Tom

HI

Depends what you want to do!

WBFM fine but pretty limited

Here in the UK we have some great transverter designs for 3cms by G3WDG
They use cheap gasfets and will give you 50mw out on 10 ghz - narrowband
They use a 2m transceiver as the if.

We have worked 1200km paths in EU with the design at 50mw - there is
also bigger amps for 300mw and !watt available - or you could drive a
Travelling Wave Tube Amplifier - I have one at 40 watts out. With a 4ft
dish you would be a BIG signal on the bands.

If you would like some more info then yell

From: fkauf@fstgds06.tu-graz.ac.at
Message-ID: <3p534h$fra@fstgds15.tu-graz.ac.at>
Source record: 112887

Where are transmitters for long wave and medium wave?
==========

I'm designing a telecommunication link at about 125kHz using only little
power. Now the receiver isn't ideal and electromagnetic fields at frequencies
of harmonics of that frequency are disturbing my receiving signal.

My questions are:

* Do you know long wave transmitters in the frequency range 230kHz-270kHz
and 355kHz-395kHz and medium wave transmitters in the frequency range
480kHz-520kHz, 605kHz-645kHz?

* Is somewhere a list of long wave and medium wave transmitters for
Europe and perhaps other countries? I'm interested in magnetic field
strength in about 10km distance of those transmitter and their location
too. If you can tell me an estimate of the transmitted power, I can
calculate the field strength by myself.

Many thanks,

Friedrich Kaufmann

What precisely in ground loss? How do you measure it?

As a general comment, I would say that this thread regarding electrically
small antennas is very interesting. Many so-called antenna experts do
not really understand these issues. Tom and Zack are to be commended.

We have some throat mikes at work which are David Clark products, which are basically little ceramic piezo elements with a voltage follower circuit after them to produce a low-Z output that can be plugged into an aircraft radio which expects a carbon mike. (Yes, modern aircraft radios exist which are _still_ designed for carbon mike inputs). The fidelity is about that of the T-1, which is to say you can usually make out every third word in usual conversation, and if you use standard prowords and repeat yourself regularly, you're probably okay. These things cost nearly a thousand bucks each and I wouldn't wish them on my worst enemy. The T-1 was fifteen bucks the last time I looked, and while I still wouldn't wish them on my worst enemy, it's a lot less money to spend to discover that it sounds rotten.

> You'll probably do better to consider an *ear* mike.
>These work by sound conduction too, and are commercially available
>to match modern radios.

The local cops use these things, and report that they work pretty well,
or at least that you can tell the difference between vowels. I haven't
bothered listening to the police radio recently, so I can't say, but they
use Maxon units that might be worth looking at.

Hey, it's even better! They worked at 1.75 MHz to be precise, so the amount of effort to move them to 160 is miniscule. Don't know why you would want to do this, but it's no worse than my attempts at getting a WAS using a Hewlett-Packard signal generator for a transmitter. (I have a long way to go, still, after eight years.)

>cordless, NOT a cellular.

Yes, there are a lot of them out now. The Tropez is the one which seems most popular in this area. Some of these use a digital link, but most of them just use standard narrowband FM. It would be fun to modify these for the ham band, but why bother? My local cellular outfit will sell you a cellular phone for $9.95 if you pay for six months of service... you use it for six months, close out the account and move it to the ham bands...

If your old ARRL manual has specs on the tube, it likely has a base diagram. The standard base diagram id for the 4-400A is '5BK'

Hold the tube so you're looking at the base. The pins are clustered roughly in a group of four, with a fifth pin out by itself. Put the 5th pin at the top. Pin numbers, reading from the top clockwise are (3) grid, (4) screen grid, (5) filament, (1) filament, and (2) also screen grid -- connected internally to pin (4). Obviously, the plate is on the top of the tube.

Oh, and I agree with the other comments about building an amp around a used tube of unknown condition. And your standard Hickok tester won't be of much use unless you have a rare base adapter to fit this tube. You'd be better off building something with a single 3-500Z (or a pair).

4-400A isn't a bad tube. I use one in a 500 watt boatanchor AM transmitter. But I don't think I'd build an amp out of one today.

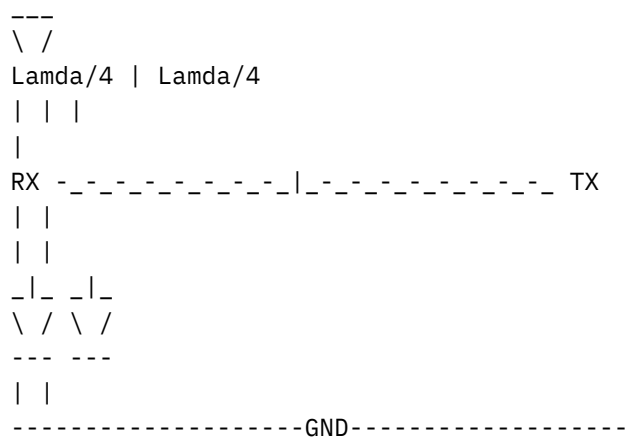
Ken Edwards (cnc23a@b4pph13e.bnr.ca) wrote:
: Will Pin-diode TR switching work up to frequencies in the 902-928 Mhz
: range ?

: If so, can anyone give me pointers on how to accomplish this..

Ken,
sure, PINs are used with some regularity up at 900 mhz.

#1)
The simplest PIN switches have PIN diodes as "series"
switches. I.E. the diode is placed in the signal path. The problem
with this is that the isolation is poor because the diodes tend to
have a large capacitance (due to their size, especially so for high
power pins). If the design is "narrowband" (most often the case), you
can actually try to resonate out the capacitance with a DC blocked
inductor in parallel.

#2)
Another type of switch is the "shunt" switch. Here, the
switch generally has two branches. I'll attempt some ascii art here:



Each of the Lamda/4 transmission lines serves the typical
purpose of "impedance inverter". If, for instance, the RX diode is
on, a very high impedance is presented to the antenna junction, thus
making the RX side "disappear". The same is true of TX. From what
I've seen, this type of switch is very popular.
I built one earlier this year for 400 MHz (for an IF switch in
a 2.3 & 3.4 GHz transverter) with some 30 watt PINs that GE uses in
their 900 mhz mobiles. With this type of switch (above), I got 24 dB
of isolation and under a dB of insertion loss (all etched on 1/16 th
G-10). I didn't end up using the thing, but it was fun for ha ha's.

As with low frequencies, one could implement the transmission lines sections using lumped networks.

#3)
The other type of switch is to combine the two techniques. Obviously one would gain the advantages (and some disadvantages) of both types of switch. The loss would go up, but so would the isolation. I didn't bother building one like that because I was too lazy to hand draw the somewhat more complex circuit board, and I didn't want to try to figure out how to model all of the device parasitics.

Hope this has been somewhat helpful. There's a good applications book by MicroSemi corp (or something like that).... if you can find their number, it would be worth asking for one...

73 & good luck
Lance

Jeff -

Of those 7,000 newsgroups, how many are totally bogus and mostly or
totally unused, such as:

alt.brian.saunders.pot.kettle.black
the whole alt.bonehead heirarchy
alt.bubba-love.el-caminoville
alt.bruce.it.was.just.an.accident
alt.butt-keg.marmalade
alt.cancel.bots
alt.check.her.miss-jesus
alt.choad

etc., etc. This list could go on and on. I'm really curious as to how
these newsgroups got started. They certainly don't serve a purpose
because nobody ever uses most of them and their names are totally wierd.

This message describes the rec.radio.amateur.*, rec.radio.cb,
rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet
mailing list counterparts and complements. It is intended to serve as a
guide for the new reader on what to find where. Questions and comments may
be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October
1994 to add the discussion of non-Usenet mailing lists and streamline most
of the history discussion, and to change the moderator information for
rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became
progressively higher. First one by one, and then as part of two
reorganizations, what was once one group became many. In the process,
developments elsewhere on the net were reflected in the groups as they were
created, most notably the change to place all of the ham radio groups in one
hierarchy.

The collection of newsgroups continues to grow as more people join the net,
and as more topics of discussion gain volume, I expect to see more groups be
created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the
notable exception being rec.radio.swap. There are also a few mailing lists
that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them,
and not to the groups that aren't. The whole idea of having different
```

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

1999. 300 Khz receiver for GPS differential

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-15 00:00:00 UTC
From: kirk@neptune.gsfc.nasa.gov
Message-ID: <3p827r$cah@post.gsfc.nasa.gov>
Source record: 112900
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave,rec.radio.scanner

The Coast guard is starting to broadcast differential correction signals for GPS navigation around the US coast. With that signal, your $300 GPS can correct its real time position from about 100 yards accuracy down to less than 10 yards accuracy. (The GPS signal itself is intentionally degraded by the Air Force to 100 yards to confuse Russian missles - the Coast Guard's differential correction merely brings it back. You figure.)

The catch is that the Coast Guard is broadcasting these corrections at around 300 Khz instead of a more sensible VHF that anyone could copy. (I'm convinced they have a warehouse full of old LF/MF xmtrs that they have left over from the old marine radiobeacon days).

Anyway, there are a couple of manufacturers selling little receivers to capture the Coast Guard broadcasts into the GPS, but at outlandish prices, more expensive than a cheap GPS by itself. My question is, does anyone know where to get plans to build a cheap, single freq 300 Khz receiver to feed into a TNC? Or is it cheaper & easier to get an old beacon rcvr or RDF at surplus or a swapmeet?

Though this area is for homebrewing, there are those who read information
from this area and not from others. Therefore, just so you don't feel
left out, I've posted a short blurb over here too. ;)

Crossposted message follows...

From helix@solaria.sol.net Mon May 15 12:44:32 CDT 1995
Article: 27243 of rec.radio.amateur.misc
Path: news.sol.net!solaria.sol.net!not-for-mail
From: helix@solaria.sol.net (Rob Radvanovsky)
Newsgroups: rec.radio.amateur.misc
Subject: Milwaukee, WI Repeater Links
Date: 15 May 1995 12:42:01 -0500
Organization: SkyNet Communication Services
Lines: 31
Message-ID: <3p83p9$brn@solaria.mil.wi.us>
NNTP-Posting-Host: solaria.mil.wi.us

I've figured out what the various links are for the Greater Metropolitan
Area of Milwaukee, Wisconsin (ya-her-day, eh?) and I feel that these
frequencies will be of great benefit to those who've had some trouble
getting into the two largest repeaters on VHF within the Milwaukee, WI area.

As these frequencies are listed within the amateur radio spectrum, those
who feel that these frequencies should be kept private are badly mistaken
as amateur radio is for everyone. Therefore, I am listing these
frequencies for everyone's use:

145.130 (output) / 144.530 (input) PL = 127.3 Hz (MAARS):

links are listed below with their guessed locations:

222.270 (output) / 223.870 (input) PL = 127.3 Hz (NW site)
222.290 (output) / 223.890 (input) PL = 127.3 Hz (main site)
222.320 (output) / 223.920 (input) PL = 127.3 Hz (UPS site)
222.340 (output) / 223.940 (input) PL = 127.3 Hz (SW site)

146.910 (output) / 146.310 (input) PL = 127.3 Hz (MRC):

links are listed below with their guessed locations:

446.525 (output) / 446.525 (input) PL = 173.8 Hz (SOUTH site)
446.250 (output) / 446.250 (input) PL = 173.8 Hz (NORTH site)

Enjoy!

Got it, Dave, it'll be on its way tomorrow. A couple of comments on the article:

The article claims "3 dB noise figures at 432 MHz without the use of a circulator," and goes on to note that this is "no improvement over the better uhf transistor amplifiers" (and remember, this was written around 1972). The article claims that the paramp shows most promise above 1000 MHz, but of course the mid-70s development of the GaAsFET (initially *very* expensive) and subsequent drop in price over the past decade have given us the low-cost preamps we enjoy today. So, to be truthful, the paramp has been overtaken by technology, but if you want to dabble in a little RF "black magic" (like, getting s stable pump signal which, for 432 MHz, is around 4 GHz; in the "good old days" this was done with a receiving-type klystron, a "black-magic" device if ever there was one..... :-))

During the late '60s I was Maintenance CPO on the USS BELMONT (AGTR-4) as an ETC, and we had the Navy's shipboard "moonbounce" or EME system, the AN/SRC-33(XN-1). The system used a 2300 MHz uplink and 1800 MHz downlink, with a 12 kw, 4-cavity power klystron in the transmitter and a 16-foot, X-Y pedestal dish with circular feed. The receiver front end had - you guessed it - a paramp, and it *was* a tricky beast to adjust, commercial equipment or not.

BTW, we ran two chnnels of 100 WPM RTTY via moonbounce to either Hawaii or Cheltenham, MD (depending on who could see the moon best); the shore stations ran 12 kw to 65-foot dishes. With input from the ship's gyro and Roll/Stabilization Data Set, our antenna would track the moon completely cross the sky from 5 degrees above horizon to 5 degrees above horizon.

It was, as we used to say, "like a landline," and to those of us all-to-familiar with the vagaries of HF propagation (especially from South America, where the nearest COMMSTA was Panama, San Juan or Gitmo) it brought tears of joy to our eyes. It was also a "window

on the future" and gave us some idea what it might be like when satcomm became a reality (now taken for granted by most, I expect).

Ahh! It's a godsend! Finally an opportunity to get rid of all these ARC-5 rigs that have been piling up in the garage!

But, if you don't want an ARC-5 set (and I think every person in the country _should_ want an ARC-5 set), you can probably just do a quick and dirty direct conversion setup. I think stealing the IF strip out of an AM table radio and detuning it down to 300 KHz by adding more capacitance to the IF cans might do the job nicely.

However, what are you going to do with the baseband when you get it? How is the signal encoded?

I don't have a program, but plug the inductance formula from the
ARRL handbook or similar source into a spreadsheet and feed it
any numbers you desire - presto, out comes the answer. A little
algebra may be needed, but that can usually be simplified in a
spreadsheet program by preforming sevveral stepwise calculations.

I'm in dire need of a good quality device programmer to do PALS/GALS and PEELs immediately, and hopefully to grow into full-fledged Altera devices in the near future. I don't want to screw around with a low cost device with comparably low performance and reliability. I'd rather spend my money up front, and save in the long run. There are a limited number of news groups for this sort of question -- being a ham, I figure it's ok for me to ask here...

Are any of you doing serious work with your software and hardware, and if so, could you share your feelings about them with me?

Cheers!

Please educate me .....

My Kenwood TS830S has begun to show its age. I've owned it since new
about 15 years now and it's output power has started to sag. It is
time to re-tube this rig.

I have seen (and skipped over) discussions regarding a tube 6146W.
Matched pairs priced at about $50. I seem to remember it was a
more robust version of the 6146B which is the stock tube in my rig.

My questions are :

a) Is this a plug in replacement for the 6146B ?
b) are the voltage current ratings the same ?
c) is $50 a fair price for the pair ?
d) are these really new tubes or NOS ?

Thanks in advance for the information.

2013. 4-400A's as substitutes for 3-500Z.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-16 00:00:00 UTC
From: Waltk@pica.army.mil
Message-ID: <9505160928.aa08862@COR5.PICA.ARMY.MIL>
Source record: 112907

The 4-400A is plug compatible with the 3-500Z. In grouded grid
configuration the tetrode is run as a triode. Recently I had the
opportunity to test 4 3-500Z's in my 4-400A amp. The only difference
I noticed was the 3-500Z is a bit easier to drive, thats to say,
it requires fewer watts to obtain the legal output than the 4-400A.

My amp is homebrew, it uses 3 (yes, 3) 4-400As. Recently I installed
some rugged pulse rated tubes (made in France) that are identical
to the 4-400A except they're rated at 500W dissipation. They came
from a "Laser cutting" machine (cuts 1/2" Stainless Steel).
The tubes are rated at 30kV max and a peak pulse power (5% duty cycle)
of 65kW per tube! They seem to loaf along at 1500W out running RTTY
(100% duty cycle). I still have 5 4-400's laying around as spares,
if and when, I need to replace the "Laser" tubes.

The nice thing about 4-400's is, as someone has already mentioned,
they are readilly available as "pulls" or at hamfests. A darn sight
cheaper than an 8875, 8874 or any of the "new" geneartion cermaic
tubes. You can put them into an SB-220 and have yourself one heck
of a cheap and reliable amp for a fraction of what it costs to get a
new generation commercial amp.

If you're serious about building an amp, look up articles in QST
written by Measures, AG6K. In my book (contrary to popular belief)
he is THE de facto expert on amplifiers. 73, have fun, and PLEASE
BE CAREFUL - amplifiers can kill!

I recently went through the same process, and it isn't pretty. The 431C is the cheap part, the thermister sensor is the expensive part. I eventually found a used sensor from one of the surplus test equipment companies that advertise in the Nuts & Volts magazine; but it cost $100 for the sensor. The cable was even harder, hp will sell one for about $150. I purchased a set of connectors for about $18.00 and made my own cable with some shielded twisted pair. The connectors are pn 91-MC6M and 91-MC6F1 (I don't remember the mfg - but I could probably chase that down)

When done, the thing works pretty good, but the sensor may be just a little flaky as I have to be careful and not move things around while I'm making measurements. If I move the sensor around it affects the zero, so I may not have a 100% good sensor.

Good Luck....the good part is that when you get done, you'll be able to measure rf signals up to around 10GHz (so long as they are low power).

There's always Data IO. They are a little pricey, but you know that you'll get support and they will still be around when you want to upgrade. They work closely with all the device mfgs so they usually support the new devices as soon as anybody (but you have to be a little careful - they don't add support for all new devices to all the programmers at the same time).

They have a better reason than that. The groundwave from the MF transmitters covers a larger area than would a VHF transmitter's LOS signal. Therefore they can use fewer transmitters. Fewer transmitters means fewer maintenance headaches and lower costs.

No, but the cruise missle with the conventional warhead might. This is
why the signal is degraded, to render the data stream unusable for long
range self guided missles of a conventional nature. Some of our cruise
missles use GPS (with the military error correction) for primary
navigation to the target.

You are unnecessarily rude. Not everyone in the world is aware that the term homebrew can apply to electronics. Given the somewhat incoherent nature of Mr. Long's original posting, it appears that he may have been under the influence of excessive amounts of homebrewed beer. Would you propose a blood alcohol limit for driving on the internet?

I really appreciated the historical information about Navy EME systems that Paul Bock related in a recent posting. As for parametric amplifiers, the AWG-9 weapons control radar in the F-14 was originally designed with an X-band parametric amplifier. Electronic systems designers in the 50s and 60s were often quite sophisticated at applying exotic technologies. Although we are much more advanced in terms of micro-electronics these days, these older designers were often able to deal with a much broader range of technology.

Yes, the designs were published in the Microwave Handbooks Vols 1 - 3
Published by the RSGB.

Speaking to Charlie Suckling G3WDG designer and organiser of the
microwave committee components service, he gave me the followig
information for non-uk parties wanting to build the transverters:

Banking arrangements have been made to accept personal cheques drawn in
US dollars, the exchange rate $1.5 to each UK pound. PLus
a banking fee of 10 dollars per order.

He is quite happy to send information out
about the designs and he can be
reached by email at
charles_suckling @ mcimail.com

Im also willing to help in
anyway I can by supplying components and hard to get items if required.

If anyone requires anymore info then please mail charlie or myself as
required.

The Microwave Handbook is listed in the ARRL Publications Catalogue
in the VHF/UHF/Microwave section. I am not currently aware of an
on-line source of data. I believe that the RSGB is NOT yet on the
Net. Good luck in finding the information.

There is nothing wrong with posting a commercial site, but a word of description is considered good netiquitte. Given the prejudice against advertising on the net, you'd think that you folks would want to do all you could to promote good will.

Just a thought,

Doug

What is popular is not always right.
What is right is not always popular.

ARRL Handbook for Radio Amateurs tells you how to calculate those
yourself. If you want a figure, you might check up a book called
VHF/UHF Manual, it has nice figures where you can eg. look as a function of
the wire diam and inductance the required turns.

I'd check the +/- rails to the deflection amp (or even before it gets there)
before I got too depressed about the CRT.

Symmetrical distortion sounds mighty suspicious for a CRT fault.

Good Luck.

>Although we are much more advanced in terms of micro-electronics these
>days, these older designers were often able to deal with a much broader
>range of technology.

Quite true, and quite often the engineering teams tasked with coming
up with new designs could be quite creative in their approaches, although
to be fair I'd have to point out the obvious fact that *sometimes* things
just didn't work out as planned. But, that's just part of the design
process - well, unless you're building an airplane, bridge, building or
elevator; then it had *better* work! :-)

Being on a "technical research ship" (AGTR is the Navy hull type
designator for "Auxiliary, Miscelleneous Class, Technical Research;" we
used to say that it really stood for "Always Going To Revolutions,"
inasmuch as we seemed to be sent to a lot of "trouble spots") we saw our
share of "new approaches" to receiving system technology, especially in
the lower microwave region. It was an interesting time to be working
in electronics.....

Regarding the EME: The Navy "concept name" was TRSSCOMM, or Technical
Research Ship Special Communications. The first such system was built by
NRL, as I recall (sort of a "homebrew" affair which would warm the heart of
any ham), and installed on USS OXFORD (AGTR-1). The dual-channel IF used
a pair of R-390A/URR receivers as tunable IFs. The antenna pedestal was
a modified 40mm gun mount. I know that a similar system was put on USS
GEORGETOWN (AGTR-2), but I'm not sure about USS JAMESTOWN (AGTR-3). The
first of the AN/SRC-33(XN-1) systems, which were built by Lockheed
Electronics, was put on the ill-fated USS LIBERTY (AGTR-5) and USS BELMONT
(AGTR-4), on which I served, got hers after LIBERTY (it was simply a matter
of which one was in the shipyard at the right time; as it happened, we
were deployed and LIBERTY was in Norfolk).

One interesting anecdote: the SRC-33 had a latitude/longitude
readout which was quite accurate, so on a couple of occasions we "needled"
the ship's navigator by calling the bridge and asking for a position just
after he'd done his evening shot with the sextant, and after he gave us the
lat/long we'd tell him where he *really* was. Of course, these were occasions

when we were tracking a visible moon, of course. BTW, in the '60s the sextant was still a primary navigation tool as (a) there were no satellites, and (b) we only had Loran A, which wasn't that accurate.

And for you EMEers out there, yes, we did point at the Sun as a check on receiver performance. Polarization, BTW, was selectable RH/LH circular or linear. Normally the ships used RH and the shore stations used LH (remembering that the polarization sense reverses when the signal bounces off of the moon). We were able to maintain solid RTTY copy while running a couple of KW, but we normally ran about 6 or 8 to allow for the occasional fade. We had to maintain the dish antenna boresight within 1.5 moon diameters of the moon's center, and we had a dish-mounted closed-circuit TV camera (with crosshairs) which was very helpful in that regard.

But for the true ham experimenter, doing EME that way would seem much too easy, and in fact it really was a "brute force" system (especially with those 65-foot dishes at the shore stations).

Gary... That's true, but if you look at the total cost: USCG transmission
cost + user receiver cost, I'd guess that x thousand users having to buy
otherwise useless, specialized LF/MF rcvrs instead of using VHF which
everyone already has on board, would tip the cost scale. Plus a better
quality, non-multiplexed, ascii signal to boot. I was hoping they'd
use the existing NOAA VHF weather broadcast sites which already provides
good coastal coverage, and use one of the unused WX freqs at that site.
(162.40, .55, etc.) That way, anyone could get differential by turning a
knob on his marine VHF at zero cost.

Ilkka has said it very well, there is NO such thing as RMS power as
a standard, accepted definition. RMS voltage and current, yes.

ilkka.kontola@nmp.nokia.com (Ilkka Kontola):

>RMS voltage and RMS current are useful ways to describe
>AC signals. A 100 V RMS voltage will heat a resistive
>load with same power as 100 V DC voltage does. That
>is the definition.

>RMS power can be calculated but it has no meaning. 100 V RMS
>voltage at 100 ohms resistive load will heat the load
>with 100 W _average_ power.

There have been some messages here that are generally correct with
regard to power measurement, *except* that each erroneous reference
to RMS power has to be replaced with *average* power to be totally accurate.

As Ilkka has so well expressed, carrier and PEP power are both defined
in terms of average power (which may be calculated with appropriate RMS
voltage and/or current values).

When the "Lab Notes" column that started this whole thread came out,
I contacted the author about missing the opportunity to bury the
misnomer RMS power, and he has informed me that there will be a followup
in QST that will clarify the issue. I hope it turns out okay.

Err, the differential receiver doesn't just dump audio into the GPS. There's data on that signal, and the data has to be recovered. I suspect it's those data recovery bits that are the hassle, and would have to be done, even if the signal was on VHF.

On the other hand, I also suspect, but don't know that, any collection of people who could put together a TNC could put together a homebrew differential receiver. As far as I know, there's no diff signals around here in the San Francisco Bay Area yet.

2038. Looking for copper pipe J-pole antenna advice

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-17 00:00:00 UTC
From: oops@msg.ti.com
Message-ID: <3pdp63$so5@superb.csc.ti.com>
Source record: 112839
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I have several plans to build copper pipe J-pole antennas. The one
I'm looking at in particular is tri-banded (2m, 1.25m, & 70cm). On this
design, three feed lines are used. Each feedline corresponds to it's own
'cactus leg' on the J-pole. I'm planning to build a dual-band version
(2m & 70cm) using the tri-bander plans. However, I do not want
to run two different pieces of coax through the house. So, I'm thinking
about using a 2m/70cm duplexer to combine both feedlines from the antenna
into one for distribution through the house. I've seen duplexers designed to
take two imputs (from a transceiver) and combine them into one output
(to the antenna). Would this same duplexer work just the opposite
(one input from the transceiver split to two outputs to the antenna)?
If not, what would be a good approach to combining the two feedlines
into one?

Thanks in advance and 73
Mitchell

The reasons for using VLF are two fold. First it can be recived at much greater distances than VHF and second it is almost immune to multipath propogation. This means that that you can have pretty high confidence in how long it took the signal to reach you. This important to correcting the GPS.

stage thingy's a tad...

I have a couple of questions and comments for our gathered host.

1) was the posting made from a commercial account? (it was my understanding
that the neticate issue had more to do with using non-com accounts for
business purposes than the use of comercial accounts for business
purposes)
I could of course be wrong.
2) As the net goes fully comercial, how are we (both as net users and
business
people) going to agree what is the appropriate use of bandwidth? I ask
this not as a retorical question, but as a potential user and comercial
maintainer. I've been considering putting my families custom tile
business on the web. So, how am I supposed to advertise our site?
although it might seem like rec.radio.* may be an inappropriate place
to advertise, who knows... We make tile for the Boyscouts, why not
amature radio groups or idividuals who want their callsigns/logos on tile
too. So how does one go about this in a net-tically acceptable fassion?
Isn't a three or four sentance blatant ad. like "would you like to have
your callsign/logo custom and hand made in tile? Check out http://..."
3) What is the neticate for those who get flammed by the Net COPS? I
personally have little to no tollerance for self appointed moral crucaders
of ________ (please fill in the blank).
.... now you can eat your spam, eggs, spam, and spam!

I whole hartedly agree with Dr. Kristin Rachael Hayward's,
hayward@cs.uchicago.edu (WX9T)... "... whether it be ham radio or the net,
there will be the OFs sitting in their shack complaining about something."

EBo --

ps: if you are so upset with the use/abuse of bandwidth, why did you keep
reposting to something on the order of 10 news groups?

2045. AM RIG and Linear KITS

Newsgroup: rec.radio.amateur.homebrew

>because nobody ever uses most of them and their names are totally wierd.

You have to understand the difference between the Usenet Big 8 and
other hierarchies, specifically alt.

Here we have votes to determine before group creation if there's
enough interest, and an individual (tale) to send newgroup messages
that will be honored automatically.

In alt, there are no votes, anyone can send a newgroup message, and
any site can choose to honor it or not.

Nobody's BOUND by Tale, here, but I guarantee you a new rec group
will get at least 50% propagation, especially if it's part of an
existing subgroup such as rec.radio.amateur. A new alt group will
be extremely lucky to get 35-40% propagation.

And the more silly alt groups that get created, the more this
divergence occurs.

The flip side is that the big commercial sites (e.g. AOL, Prodigy,
Netcom <g>) newgroup practically everything that comes down the pike,
so that a large percentage of Usenet readers do have access despite
low propagation.

:

That's what most people mean when they say "RMS power": power averaged
over one complete cycle, and calculated *correctly* using RMS voltage
and/or current values.

I don't think too many people believe that you take the RMS value
of the power itself, because that's well-known to give an *incorrect*
result.

In other words, "RMS power" is a shorthand usage, not an unambigous
technical term. It has come into use - and sticks around - because
it has some real value in reminding us that the power has been
averaged over a complete cycle.

The technically correct term, "average power", is no less ambiguous
or open to misapplication... was that averaged over a cycle, a second,
a week or what?

A couple of years ago I was hauled over the coals for using the
term "RMS power" in my magazine column. As you see, I'm not
entirely repentant.

: When the "Lab Notes" column that started this whole thread came out,

>Lawrenceville, GA 30244 | |

Gary... That's true, but if you look at the total cost: USCG transmission
cost + user receiver cost, I'd guess that x thousand users having to buy
otherwise useless, specialized LF/MF rcvrs instead of using VHF which
everyone already has on board, would tip the cost scale. Plus a better
quality, non-multiplexed, ascii signal to boot. I was hoping they'd
use the existing NOAA VHF weather broadcast sites which already provides
good coastal coverage, and use one of the unused WX freqs at that site.
(162.40, .55, etc.) That way, anyone could get differential by turning a
knob on his marine VHF at zero cost.

Bob Kirk
N3OZB

I'm not sure about the great range from those MF beacons in the real
world. Years ago I used them for dfing, but they seemed noisy and
not terribly long ranged. But time clouds happy memories. :-)

I don't have a program, but plug the inductance formula from the
ARRL handbook or similar source into a spreadsheet and feed it
any numbers you desire - presto, out comes the answer. A little
algebra may be needed, but that can usually be simplified in a
spreadsheet program by preforming sevveral stepwise calculations.

I recently went through the same process, and it isn't pretty. The 431C is
the cheap part, the thermister sensor is the expensive part. I eventually
found a used sensor from one of the surplus test equipment companies that
advertise in the Nuts & Volts magazine; but it cost $100 for the sensor.
The
cable was even harder, hp will sell one for about $150. I purchased a set
of
connectors for about $18.00 and made my own cable with some shielded twisted
pair. The connectors are pn 91-MC6M and 91-MC6F1 (I don't remember the mfg
-
but I could probably chase that down)

When done, the thing works pretty good, but the sensor may be just a little
flaky as I have to be careful and not move things around while I'm making
measurements. If I move the sensor around it affects the zero, so I may not
have a 100% good sensor.

Good Luck....the good part is that when you get done, you'll be able to
measure rf signals up to around 10GHz (so long as they are low power).

Subject: Need information on a Valve

Please educate me .....

My Kenwood TS830S has begun to show its age. I've owned it since new
about 15 years now and it's output power has started to sag. It is
time to re-tube this rig.

I have seen (and skipped over) discussions regarding a tube 6146W.
Matched pairs priced at about $50. I seem to remember it was a
more robust version of the 6146B which is the stock tube in my rig.

My questions are :

a) Is this a plug in replacement for the 6146B ?
b) are the voltage current ratings the same ?
c) is $50 a fair price for the pair ?
d) are these really new tubes or NOS ?

Thanks in advance for the information.

Subject: PEP measurement

Ilkka has said it very well, there is NO such thing as RMS power as a standard, accepted definition. RMS voltage and current, yes.

ilkka.kontola@nmp.nokia.com (Ilkka Kontola):

>RMS voltage and RMS current are useful ways to describe
>AC signals. A 100 V RMS voltage will heat a resistive
>load with same power as 100 V DC voltage does. That
>is the definition.

>RMS power can be calculated but it has no meaning. 100 V RMS
>voltage at 100 ohms resistive load will heat the load
>with 100 W _average_ power.

There have been some messages here that are generally correct with
regard to power measurement, *except* that each erroneous reference
to RMS power has to be replaced with *average* power to be totally accurate.

As Ilkka has so well expressed, carrier and PEP power are both defined
in terms of average power (which may be calculated with appropriate RMS
voltage and/or current values).

When the "Lab Notes" column that started this whole thread came out,
I contacted the author about missing the opportunity to bury the
misnomer RMS power, and he has informed me that there will be a followup
in QST that will clarify the issue. I hope it turns out okay.

I'd check the +/- rails to the deflection amp (or even before it gets there)
before I got too depressed about the CRT.

Symmetrical distortion sounds mighty suspicious for a CRT fault.

Good Luck.

There's always Data IO. They are a little pricey, but you know that you'll
get support and they will still be around when you want to upgrade. They
work
closely with all the device mfgs so they usually support the new devices as
soon as anybody (but you have to be a little careful - they don't add
support
for all new devices to all the programmers at the same time).

Subject: Re: A cheap microwave transceiver?

Yes, the designs were published in the Microwave Handbooks Vols 1 - 3
Published by the RSGB.

Speaking to Charlie Suckling G3WDG designer and organiser of the
microwave committee components service, he gave me the followig
information for non-uk parties wanting to build the transverters:

Banking arrangements have been made to accept personal cheques drawn in
US dollars, the exchange rate $1.5 to each UK pound. PLus
a banking fee of 10 dollars per order.

He is quite happy to send information out
about the designs and he can be

reached by email at
charles_suckling @ mcimail.com

Im also willing to help in
anyway I can by supplying components and hard to get items if required.

If anyone requires anymore info then please mail charlie or myself as
required.

Well, they DID have a number of existing radiobeacon sites still in operation.
We had to resurrect a few radiobeacons to implement our system.

>>
>>They have a better reason than that. The groundwave from the MF

Gary is right. The coverage is excellent. Also, when the USCG looks at
their clients, it's primarily marine shipping that *needs* DGPS. If they
run aground, the repairs cost millions, and there can be environmental
ramifications, and they are paying the bills, after all. (with port fees,
registration, taxes, etc.)

>
> Gary... That's true, but if you look at the total cost: USCG transmission
> cost + user receiver cost, I'd guess that x thousand users having to buy

Again, you have to look at the user base. It's *want* vs. *need*.

Now some enterprising ham might want to take the bull by the horns and
develop an *el cheapo* MF differential receiver to sell to the yachty
crowd and silly sailors.

>
> I'm not sure about the great range from those MF beacons in the real
> world. Years ago I used them for dfing, but they seemed noisy and
> not terribly long ranged. But time clouds happy memories. :-)
>
The beacons are quite difficult to receive aurally, but the MSK signal for
differential corrections are quite another matter. Close to 200 NM radius
effective coverage over water, in many instances, although the advertised
service coverage may be less.

2052. HELP, army surplus 6m handie align?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-18 00:00:00 UTC
From: rpmackin@ashley.business.uwo.ca
Message-ID: <3pfi0d$ns6@falcon.ccs.uwo.ca>
Source record: 112853

I bought a pair of 6 metre radios at Dayton.
They are Army surplus units, the rx clips on a helmet, and the tx is handheld
with 2 channels.

Receiving set, radio, AN/PRR-9
Transmitting set, radio, AN/PRT-4 (or 4A)

I know what formula to use in re-crystalling the units, but I need alignment
info.
The book makes reference to a service instruction guide;

TM 11-6625-937-12, for the alignment procedure.

I also would like to know if there is a easy way to allow a
carrier squelch to operate in the rx unit,
it currently has either PL(150Hz) or open speaker modes.

Any help would be greatly appreciated.

Thanks!

2053. Old radar detectors as 10G xmit/rcvr?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-18 00:00:00 UTC
From: "Dale Botkin, N0XAS" <dbotkin@probe.net>
Message-ID: <3pfm74$4g8@jake.probe.net>
Source record: 112854

I've got a couple of old unused radar detectors lying around. I know one is X/K band, and I think
the other is as well. The one I have disassembled in front of me apears to have two Gunn diodes
(I think they are, anyway) and two tuning screws. One is in a cavity in the rear, the other is
poking into the horn about an inch or so in front of the first.

Anybody know what I'm looking at here? Is there a source of articles, FAQs, or other information
to help me figure out how to homebrew a 10G transmitter, receiver, and/or transceiver from these?
FM would be nice, but I'd settle for CW just to experiment with. I keep hearing people saying
there were "some magazine articles a few years back", but have yet to see anything at all on this.

That's already been done. W3IWI has broadcast a differential correction
at a VHF ham freq (145.79) with a standard output that can go directly
into an existing TNC on into the GPS. Worked like a charm. one line
every 30 seconds or so didn't even interfere with the APRS packet
traffic. Same TNC, same VHF radio. (I wish he'd make it permanent.)

2055. Battery charger

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-18 00:00:00 UTC
From: parkerbk@sd2.af.mil
Message-ID: <3ped4t$b72@blackbird.afit.af.mil>
Source record: 112856

I would like to build a drop in battery charger or better
put a quick charger, can anyone help. Any one got any
ideas on this, done it before, or have schematics? Currently
I use the power supply that came with the radio for charging,
(input ac120~60 Hz 3w, output DC 13.5v ___ 70mA).
Gets me kinda wondering if I could use the old 6 amp (car battery)
charger and clip the leads onto the battery pack for say 1 hour.
hmmmmmm would this work? The battery is 6v 600mAh . would it
be necessary to set the charger to 6 v instead of 12 (curious about
this because of the above charger)? I just can't caugh up
$80-90 bucks for a REAL one right now.
Thanks for any help.

There is super precise time built into the basic GPS signal from the
satellite.

A good reference is GPS documentation that comes with APRSxx.ZIP
available from, inter alia, ftp at tapr.org. See the file GPS.TXT
buried in the README subdir when you unZIP APRSxx. (APRS is a great
program itself).

Keith,

I'd like to see this. The battery would explode within minutes.

To quickcharge the batteries they have first of all to be designed
suitable.

Here in electronic mags hundreds of chargers have been published
lately, surely you can find one.

Source record: 112768

Walt,
I really didn't intend post this in public. My comments to you were private E-Mail, but you obviously felt obligated to post some of them publicly.

>What is it about Measure's published work that you disagree
>with?

I object to technical inaccuracies and publishing opinions without valid foundation. A few published suggestions were good (i.e. using a diode to anchor the B- rail), most theories are very questionable (i.e. parasitics, filaments, and photons from space radiation triggering arcs in amplifiers on standby), and some suggestions are actually harmful (i.e. using fuses to protect grids and using HV keying lines).

When questioned the author's standard reply is that his suggestions are correct, and disagreement is only because of a conspiracy to build bad products.

The ARRL became unsure of the technical accuracy of the articles so they sent copies of his work to a group of independent (not related to amateur radio) outside experts that read like a "who's who" in engineering. The *unanimous* response was that the articles had no technical merit.

I've offered to debate Rich one on one in a public forum with only two restrictions 1.) we leave personal attacks completely out 2.) we address one issue at a time until concluded before bringing in a new issue.

>Are you perhaps an purveyor of commercial amplifiers?

Ahhh, there's the start of the RM conspiracy defense. No, personally I am not. (I misunderstood "purveyor" in our private E-Mail.) I am and have been employed in the industry for a very long time. I design amateur, medical, and industrial RF and analog equipment. My real interest in this is in seeing people receive accurate and useful information, and that they learn something in the process.

: Motorola MC145146 Synth. IC. Thank you.

Try page 5-22 of Motorola's CMOS Application Specific Standard ICs
book.

From what I can see, the 145146 appears to be a single PLL with 4 bit
data bus and support for dual modulus prescaling. On-board reference
oscillator is also supported. To use it, you'll need to add reference
crystal, digital control, external VCO and external prescaler if
operation is to be above 15 MHz or so. Depending upon the application,
you may want to also add a loop integrator/filter.

I'm way out of expertise on this (as well as much else), but while the
timing of the original GPS signal is critical - and precise, I don't
think it makes much difference in the time of arrival of the differential
since the SA jiggling is only relatively slowly varying. Updates every
30 sec seem fine.

>product detector for AM? Or is there something different about the
>Quadrature detector from a straight mixer. (Aren't they both
>multipliers?)
>--------------------------------------

Nathan,

The problem is that these chips have hard limiting IF amplifiers, so the
AM/SSB would be wiped out. It might work on CW, though.

It's also possible to receive AM by listening to the RSSI output.
Distorted, but intelligible. Or you can linearize it by some external
circuitry - there was an article in 'RF Design' a year or so back
describing this approach, using, I think, a Signetics NE604.

Dale Botkin, N0XAS (dbotkin@probe.net) wrote:
: I've got a couple of old unused radar detectors lying around. I know one is X/K band, and I think
: the other is as well. The one I have disassembled in front of me apears to have two Gunn diodes
: (I think they are, anyway) and two tuning screws. One is in a cavity in the rear, the other is
: poking into the horn about an inch or so in front of the first.

The one the back is probably the Gunn diode. You can probably find out for sure by powering up the radar detector measuring the DC voltage. You ought to see 7 to 11 volts. If you run the diode off a LM317T regulator, you can FM it by feeding audio into the adjustment terminal. Keep in mind that the field strength at the mouth of the waveguide can be rather high--maybe even worse than standing next to a big dish feed with a full watt or two! Looking into the waveguide while its powered up isn't recommended--even if its just a receiver.

You can hook up a Wide band FM receiver to the other diode to make a Gunnplexer. I published a suitable receiver in the Nov. 1994 issue of QEX.

The final step is getting the units on frequency. It may be just a matter of tweaking the tuning screws. I don't know the details on your unit--I've never owned a radar detector. Perhaps the easiest way is to borrow a Gunnplexer known to be on the right frequency and tweak your unit till they talk to each other. Unlike door openers (10.525 GHz), I think these units are up around 11.5 GHz, so they can use a 1 GHz scanner and cover 24 GHz via harmonic mixing. Thus, you may have a lot of tweaking to do.

Now TWICE the number of outdoor Tailgate spaces are available...

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
May 21st, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

I always thought the 6146W was the ruggedized version of the 6146A,
not the 6146B. The "A" has a plate dissipation rating of 25 watts,
versus 35 for the "B". Unless I'm wrong, or they've updated the "W"
version, you're better off with the 6146B.

RG213U 50 1.6 9 66 " 5
RG214U 50 1.6 9 66 " 5
RG217U 50 5.8 7
RG218U 50 3.8 11Kv
RG219U 50 3.8 11
RG223U 50 3.1 16.5 66 " 1.9
RG225U 50 7.5 5
RG9U 51 1.6 66 " 5
ethernet 50 1.2 78 (foam) 0.6
22B/U 95 twisted pair 2.1 66 (poly) ?
twin lead 300 0.8 <-worse when wet! 80 (poly) ?
8281 75 9.2 2.9
9913 50 4.5 0.6
9914 50 6 0.6
8218 75 20 0.6

these are all the RG#'s I found. The attenuation curves generally follow a straight line when drawn on log-log graph paper. The slope is such that a coax with 2dB at 50Mhz will be 0.8 at 10Mhz. Most coaxes have about the same slope. So, one need only look at the same freq when comparing attenuations when selecting which coax you're gonna use from under the shack table (not strictly true, but close enough for "goverment" work! :-)). Voltage ratings: note that foam dielectric cannot take as much voltage as solid dielectric.

2079. Re: Wide tuning range VFOs

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-20 00:00:00 UTC
From: elctricman@aol.com
Message-ID: <3plftn$bjh@newsbf02.news.aol.com>
Source record: 112780

You are correct but what should be considered is the spurious from the dds will be mulitplied by 20log. For instance if the dds has a spur that is -70 dBc and you mulitiply by 50 the spurs will rise by about 34 db. You can use a very narrow loop to help filter the spur but the noise outside the loop may rise.

2080. HomeBrew Pagers

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-20 00:00:00 UTC
From: zlester@athena.cs.uga.edu
Message-ID: <3pll31$2l7@hobbes.cc.uga.edu>
Source record: 112781

Is it possible to modify a pager to make it receive pages from ham radio freqs? I have an alphanumeric pager that says it operates on 929.8625mhz. Isn't that close to the cb range? It sure would be nice if I could setup my own personal paging service. $20 per month is way too much for a simple service like this. And no I will not be using the pager for business purposes. I plan on having my email "beeped" to me.

Where can I get a list of all the freq's and what they are used for? Is there such a source on the net?

Thanks,
--

>30 sec seem fine.

I was under the impression that SA was implemented by injecting pseudo-noise in the signal. While the *average* delta might be slowly changing, any given reading could be the maximum dither distance from the previous or following reading in a pseudo-random number fashion. That means the correction transmited only applies to the particular coincident reading taken at both the reference and mobile station locations. It might represent a maximum error in position if applied to the preceding or following reading.

2082. PC Board Material

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-20 00:00:00 UTC
From: dsweeney@vt.edu
Message-ID: <dsweeney.5.0014D639@vt.edu>
Source record: 112783

At our local hamfest, I bought several pounds of scrap printed circuit board material. However, the vendor told me that, in the future, such material would be very difficult to obtain. This because a change in EPA requlations prohibit the sale of such material except only to "certified" scrap dealers.

Does anyone know anything about this?

Dennis Sweeney (WA4LPR)

2084. Help with Dead Kenwood TS-520

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-20 00:00:00 UTC
From: paulbreed@aol.com
Message-ID: <3pm4e2$dfk@newsbf02.news.aol.com>
Source record: 112785

My 8 year old son played with my TS-520 while the antena was disconnected
from the Antena Tuner and now it is dead on transmit.

The symptoms are.....
RX works fine.
No ALC indication at all while trying to Tune.
Meter Readings while trying to tune:
HV 900V
IP 0
ALC 0
RF 0

If you switch from tune to CW then the only difference is a change in the
IP fro 0 to 50ma.

Does anyone have a service manual for the TS-520?
Can I beg or Buy a copy. I have a good set of Meters Scopes etc..
availible, but I bought the rig at a Flea market and have no documentation
of any kind.

The rig worked fine before it's encounter with child.

Paul Breed

W> I always thought the 6146W was the ruggedized version of the 6146A,
W> not the 6146B. The "A" has a plate dissipation rating of 25 watts,
W> versus 35 for the "B". Unless I'm wrong, or they've updated the "W"
W> version, you're better off with the 6146B.
Jack-
I believe you are correct about the relationship between the A,B and
W. Also, I recall reports that the 6146A had lower "noise" than the B,
when used in a Repeater.
There is one other difference between the A and B: The B version has
the plate cap welded, while the A version has it soldered. One of the
more common failure modes I've encountered, has been crystalization of the
solder at the plate cap. Re-soldering with ordinary 60-40 tin/lead solder
doesn't hold up long. I've never had such a failure using the 6146B.
Therefore, if the 6146W ruggedization involves welding of the plate
cap, and the story of lower noise is true, it might be a better choice for
use in a repeater. Otherwise, I would agree with using the B version,
since it is probably much easier to find, and would probably last longer.

>for something pretty inexpensive..Any suggestions?? Thanks in advance and 73
> Keith-AC6CX topanga@li.net

AM linears are rather horribly inefficient. You'll come out cheaper
and better doing direct plate modulation at the desired power level.
While there are still some very old transmitters floating around that
work at this power level, some old Vikings and such, you're going to
be hard pressed to find newer amateur equipment working at this power
level on AM.

What you're looking at is building a moderately high power MOPA
transmitter and plate modulating it. While this is not a very
complex project, some of the components you'll need, such as the
modulation transformer, may be a bit hard to find. You'll find
this project easiest to implement with tubes, but there are some
clever, but fairly complex, ways to do it with solid state components
operating Class D. Cheap it won't be unless you're a very good
scrounger.

S T R A W B E R R Y M A N T R A R E C O R D S

To get zines distributed, Email us at the Email address below with a sample article and a description of the zine, or maybe even the whole zine, so we can make sure we want to distribute it, and if we say kuul, then send us some copies of the zine and yr in the catalog. To get yr tapes distributed-Be good, and have nice sound quality. Send a good-sounding master tape and a master cover we can make black and white copies from to the address at the bottom. If you don't send a master cover, we'll just make one. Don't expect great artwork. John's taking drawing class. We'll see what he can do. At least send a song list. The more you rock, the better. No Extreme-Hole Hearted Mr. Big shlock rock, please. We don't want Country or Offspring or Contemporary or R & B or Reggae or Rap tapes. So don't send them to us. If we don't like them, we put them away. Have any or all (?) of the following elements in yr music: rock, catchy rock, punk, or hardcore. Don't be lame, and, like we said, have nice sound quality.

Our royalty policy is real simple: When we distribute you, for each copy of the album you sell through us, (whether it's on vinyl or tape or cd) you get a dollar. Our royalty policy on zines is simple, too. You keep 70% of the money, we keep 30% of the money. If we (as in you and us) decide yr zine will be two dollars, we keep 60 cents for each sold zine. (60 cents just about covers postage costs. the zine department is really non-profit) The remaining $1.40 is yours! Because of this policy, we don't buy wholesale copies of zines in advance. mainly cos it's risky to us and yr zine gets more money this way.

*Online Zines: Don't wanna wait for snail mail to bring the zine to you? Kuul! We'll Email it to you. Just send the money to the label address telling what zine you want and where we Email the zine to so you can download

it-and
the zine will be yours within seconds of receiving the money via a
download
file. Available when the catalog specifies "Online Version." Some zines
are
available Online only, some only by mail, some both. The royalty policies
for
Online Zines remain the same. (yes, postage costs don't exist when you
send
online zines, but really, it's not fair to the non-online zines. Some of
those zines have pictures and stuff, especially art/comic-type zines,
which
would be way impossible to do online. They don't have the advantage of not
paying for copying costs and postage. Just cos they have pix doesn't mean
they should lose money.)

SoundClips from Strawberry Mantra Records. Download 20-45 second long
samples as Wave Files from Strawberry Mantra releases.

Email the screen name below to request a SoundClip. I M P O R T A N
T!!!-Must
have a sound card to play these things. If you need help, after getting yr
clip, email me, i'll do what i can. Realize that mucho sound quality has
to
be sacrificed to make SoundClips possible, and that SoundClips do not at
ALL
represent the sound quality of Strawberry Mantra releases. If AOL said
"Welcome" when you signed on, then you probably, (unless yr sound runs
through that internal PC speaker that the modem noise comes through) can
play
these things.

All prices include tax and shipping and handling.

If you run a little label yrself, contact us. We'll trade tapes and
stuff.
We make sure the sound quality is nice on our releases. And, to smaller
bands, four-track recordings are just fine. There's a lot you can do with
four track recordings to make them sound really nice. We focus on the
music.
That's why we give the bands the extra money, to bring out new material.
It's
really money out of our pockets. But we're nice. We just want to make sure
we
don't make ourselves look bad by releasing poor-quality recordings. That's
all we ask. So talk to us! See ya later.
From John Mulhausen and Andrew Bales-Owners

Email SbryMantra@aol.com
Send zines, tapes and orders (cheks payable to John Mulhausen) to:
Strawberry Mantra Records
P.O. Box 701805

Tulsa, OK 74170-1805

COMING SOON
about 20 new albums are scheduled to be sent to us
The Video- a VHS tape w/ atticus finch, john, and others live. sketches, and
behind the scenes looks at kitty vamp and strawberry mantra records. probably
will cost 7 bux
Psychedelicatessen- Strawberry Mantra is putting together a compilation that
will be sent to 14 eager radio stations. (scary) and will include at least one
song from every band we distribute. (cept the ones on the kitty vamp
compilation, of course) and if yr on the label yr on the comp. and it's going
to 12 radio stations who happen to be rather interested in us. scary....
zines galore. zines zines zines
tell me right now if you want to be updated. we're gonna bring out good
stuff, but give us a second, the label is as of now, about 2 weeks old.

You mention the bias diode method, and an active regulator method. I think it would be better to use the active regulator, because less idle current is drawn. The basic diode method is fine, but you have lots of current flowing through the series resistor and diode that is not destined for your transistor bases. It of course has the advantage of super simplicity. But I think you'll be happier with an active regulator with an adjustment pot so you can set bias to your liking; you'll get less wasted DC current to boot. I'll be building up the 140 watt amp kit from CCI, which uses the Motorola AN762 design.

>> /// Gnd

--
Theory:

The Input & Output resistors act as load for the input and source for the next
stage off frequency. The further off frequency you get the more series
reactance
and lower parallel reactance which pulls the resistors to ground.

At Fo the Series LC shorts out the resistors allowing the next stage to act as
the load for the previous stage whereas the Parallel LC acts as an RF bloack to
ground.

Increasing Q will increase the side attentuation but component values start to
become impractical.
Now I don't claim to be the originator of this circuit...first saw it in the
ARRL Adavnced Solid State Design manual many moons ago if I remember correctly.

Using these sections as building blocks, you can break down any
bandpass filter into second order sections and construct it with
the circuit above. It is part of a class of circuits known as
"constant resistance lattices". The lattice from which this circuit
is derived can be transformed to the bridged T shown above.
The general design constraint is that the product of series arm
impedance times the shunt arm impedance must equal Zo squared.
You can add a capacitor across the series coil and a capacitor
in series with the shunt coil to form transmission zeros if you
want to build an elliptic function filter or a bandstop filter
(which requires a pair of zeros on the jw axis at the center
```

frequency).

When I build filters like this, I build a constant impedance filter
to get the first 20 dB. and then follow it with a wider bandwidth
conventional filter of the reflective type. Any out of band reflections
are attenuated 40 dB. by the round trip thru the constant impedance
front end filter, for a reflection coefficient of .01, which is
probably better than the constant impedance filter is to begin with.
This saves a bunch of parts. For example, you build a two pole 5%
BW filter with constant impedance. It's down 20 dB. at 10% BW. So
you follow it with a 7 pole conventional filter with 10% BW.

A completely different way to make a constant impedance filter
is to build a diplexer and simply terminate the unused port in Zo.
The way you build a diplexer is to design complementary "singly
terminated" filters and connect the Ro=0 ends in parallel. A
singly terminated filter is one which is designed to go from a voltage source
(Ro=0) to Zo <> 0. Zverev has tables for them. For example, build
a 100 MHz. bandpass filter with 5% BW and a 100 MHz. bandstop filter
with 5% BW. Connect the Ro=0 ends in parallel and that's one port
of your completed filter. The other port is the 50 ohm port of the
bandpass filter, and you put a 50 ohm dummy load on the 50 ohm port
of the bandstop filter.

Does anyone know know of the configuration, or better still design-equations or software for designing contant impedance filters. I'm looking to make a band-pass filter, centre =100MHz, bandwidth = 5MHz, that presents a good match to 50 Ohms over a wide frequency range - preferably DC to 1GHz.

Most filter types reflect the unwanted signal, so present a high VSWR in the stopband. I want a filter that absorbs (hence has resistors) the unwanted signals.

The filter is required to be on the IF port of a mixer. I dont want to reflect the image frequencies back to the mixer. Since the receiver is wide band, I cant say what the image frequency will be - it will vary.

I am looking for specs on a Mulllard 7534 / E130C vacuum
tube. Plate dissapation, filiment voltage, pin outs would
be helpful.

Thanks-Chuck

There are "Constant Impedance BPF" sold by Mini-Circuits, and theres a simple circuit for them, but they are broadband and not real sharp. I use them quite often in my homebrew gear as terminations for the sharp BPF's and at Mixer ports.

Basically circuit looks like this.

Zo = 50, 75, etc. For Q = 1

For higher Q => Xc(ser)*Q Xl(ser)*Q
Xc(par)/Q Xl(par)/Q

```
Xc = Zo Xl = Zo
Input -----||-----UUUUUU--------- Output
| R=Zo R=Zo |
|--/\/\/------/\/\/--|
|
|
------
| |
| C
--- C
Xc=Zo --- C Xl=Zo
| C
|____|
|
|
---
/// Gnd
```

Eddystone 830/7 receiver in excellent condition. A few scratches
but very nice. Have a full set of spare tubes and manual.
This model last tube receiver made by Eddystone. Rare here in
USA. $600 OBO plus shipping.

I saw an interesting idea for an application of 3 dB hybrid couplers. Use two
couplers. The first is essentially a power splitter. Place identical filters in
each leg and use the second coupler as a combiner. Reflections off both couplers
will go to the termination at the isolated port of the first coupler, provided the
filters are identical. Signal in the passband will appear at the sum port of the
second coupler. If you just want a peaked response, the filters could be simple
resonators. There may be a simpler way, but this seems to be pretty clever.

Just considering past numbering sequences that Motorola uses for CMOS ICs it
is more likely that another source would have been the 45146, no the 5146.
Motorola took the original 40xx cmos numbers and called them 140xx, then took
their own proprietary parts and called them 145xx, letting other mfgs use the
corresponding 45xx when they second sourced Motorola. I don't have much info
on the MC145146, but have you tried the Motorola Literature request line at
(800) 441-2447

Motorola reorganized the data books for the communications ICs; the
PLLs all appear in the Communications Data Book, order #DL136/D.
Well worth having, it includes several classic app notes/article
reprints on PLL design.

: AM/SSB/CW, could I feed a 455khz signal into the Quadrature detector
: instead of the phase shifted IF signal? Would it then act as a
: product detector for AM? Or is there something different about the
: Quadrature detector from a straight mixer. (Aren't they both
: multipliers?)

You can't do this because of the fairly mundane reason that in the Motorola chips, the multiplier inputs are connected together with a low value on chip capacitor used as part of the phase shift network, so both are fed by the output of the IF, which as another poster said is hard limited.

Some of the similar Philips chips have exernal inputs on the detector and use an external phase shift cap. NE605, 615, 614.

Another trick is if there is a signal strength indicator output, you can linearize it with a antilog amp and detect AM with an FM IF strip.

Finally, there was a project a year or three back in QST for a synchronous AM detector that used the hard limited IF output to feed a seperate mixer (An NE602).

Well, guess what I just found in the Chicago area.
A signal on 322 kHz, transmitting some kind of low-rate FSK
data with a rather low frequency shift. So low, in fact,
that without the BFO turned on, it sounds like an unmodulated
carrier, not the "galloping hoofs" of an SW RTTY signal.

This is a new station, not an existing aircraft beacon. It has no
A2/MCW Morse ID modulation as those do.

Baud rate seems to be around 100 or maybe a tad more.
Might this be a GPS differential broadcaster?

PS: Haven't DF'ed it yet -- could use my classic Raytheon DF
portable to get a bearing from Wheaton, IL.

In fact, you can build this with one resistor, but then only
one port is constant impedance. (Zobel described that around
1923). Why put up with the headaches that causes when resistors
are cheap?

2119. Bias circuits for solid state amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-22 00:00:00 UTC
From: zardoz@ornews.intel.com
Message-ID: <3pqggf$5p4@ornews.intel.com>
Source record: 112813

I am getting ready to convert a class C solid state VHF amplifier
to class AB. I've been reading a few books including the RSGB
VHF/UHF manual and the Motorola RF power data book. My ARRL books
have little to say about this. It seems like there are a couple of
ways to do it:

Use a diode or transistor with base-collector tied together.
Mount it against the heat sink or power transistor. Series connect
it through a resistor adjusted to provide the desired current which
can either be predicted or tweaked.

Use some kind of active voltage regulator with a reference diode or
transistor mounted to the heat sink.

Are there other ways? Which is best and what problems are possible?
I thought I would use the base-collector tied transistor and adjust
the resistor for about 50-100 ma. idle current. My amp has an MRF6084
driving a pair of MRF4070's. I would use a separate bias circuit for
the 6084 and a common one for the 4070's. It pulls about 22 amps total
at 12 volts.
Thanks for any help.

>distance from the previous or following reading in a pseudo-random
>number fashion.

well, i'm not familiar with the exact details -- it is no doubt someone's
State Secret -- but this doesn't resemble my experience. if you watch the
a fixed receiver, the display shows a very slowly moving position. typically
under a metre per second.

this kind of "low frequency" noise allows fairly accurate course/speed
estimates. if the noise was "high frequency" it would be almost impossible
to tell if one was moving or not via GPS alone, and indeed, any dGPS
would become quite a bit more difficult -- certainly for the current US/Canada
Coast Guard system, which, i believe, transmits corrections at something
like 50bps.

(paranoia mode on) and given the claimed purpose of SA, using low-frequency
noise makes some sense too, since it pushes the integration time up for
"precise" positions. if we want, say, a position to 10m, the present system
requires almost 1000 observations (20 minutes or so for my receiver), or
equivalently, we ignore about 9 of every 10 observations. reason: successive
positions are highly correlated -- ie, not "independent".

so paradoxically as it seems, the more noise in the signal, the more useful
the system may become in a tactical environment. (paranoia mode off)

2121. Quality of automobile DC power?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-22 00:00:00 UTC
From: griff@ssd.intel.com
Message-ID: <3pqodd$km1@news.ssd.intel.com>
Source record: 112815

I've heard there may be large voltage spikes on the 13.8 volt DC power in an automobile due to alternator/regulator switching (or something like that). Does anyone know if this is true?

I want to operate a TNC (MFJ-1270B/TNC-2 clone, laptop computer, and a GPS receiver/Garmin GPS-45) while mobile. Assuming all of these devices are designed to operate within the normal range of automotive DC, should I have any concerns about connecting them directly to the power cable that I use with my current ham transceiver which is directly wired to the automobile battery? Or, should I build a filter circuit to protect these devices from power glitches (I'm not talking about alternator wine or ignition noise)? Any plans for specific filter designs to do this job would be greatly appreciated. Do the DC filters sold by Radio Shack and others for filtering noise for automotive sound systems also remove voltage spikes?

Thanks much in advance.

>
Don't think that's the way it works. At any one location the reading stays pretty constant, and if the error were really like noise it would seem like you could just average a lot of readings to get a more accurate fix. However, like some of the others on this thread, I don't claim to know that much about the system. In any case, as has been stated before, the reason for using LF is more likely propagation related, especially around inland waters where accuracy is more critical anyway.

Have a nice day.....Jay

Griff,

Head down to your closest marine electronics shop. They will have a real nice selection of D.C. power filters. Just get a current rating large enough to do the job. Newmar electronics filters is one company that comes to mind, there are many other good companies too. Have used these filters for removing noise and usually work fine. The automotive D.C. system is well regulated, however the starter motor can cause large voltage spikes as can other motors in the vehicle. A good D.C. power line filter will assist in elimination of there troubles. Also a good direct cable to the battery, which acts like a filter anyway.

Don't forget, the one main advantage to using a diode to provide bias is that it provides temperature compensation. As the temperature of the output transistors goes up, the base-emitter voltage drop decreases (or another way to say it, is that the bias current achieved with a constant bias voltage will go up as the temperature goes up). This can lead to thermal run away; as the transistor gets hotter, it draws more current which makes it even hotter. The bias generated by a diode which thermally tracks the temperature of the pass transistor will decrease as the diode temperature goes up, thereby providing at least some compensation.

Source record: 112732

But remember that the bias current through the diode has to exceed the peak base current several times over or else the bias will wiggle around with drive. That will cause gain compression, splatter, and distortion (as many VHF/UHF operators living near people using diode biased amplifiers can attest to).

It is almost impossible to place enough standing current in a simple diode bias circuit for good linear SSB operation at power levels over a few watts. The best circuits use a temperature sensing device along with an active regulator.

If the transistor has a current gain of 10 at the operating frequency, and draws 20 amps of peak collector current, the bias diode would require at least 10 amps of standing current to remain relatively stable, since the peak base current would be 2 amps! The bias current tries to push the transistor into cutoff, so you sure don't want it to wiggle much.

I am building a UV timed exposure unit, for exposing printed circuit boards. I have two 12 inch florescent tubes in parallel, and switched by a relay, by a timer circuit. My question to anyone who could help me, is do I need contact suppressors accross the relay contacts, and if so how are they to be wired into the circuit.

I would be very grateful for a answer to this querie.

Best Regards
Alex

I've had some personal experience with this. On my Subaru station wagon when you turn off the ignition while the lights are on, the lights go off. And the lights don't come back on until you turn the ignition back on (or to "run"). I went through about 4 headlights ($15/each) in 2 years, on both sides. Then I started turning off the lights before turning off the ignition, and I haven't had to replace a headlight in 3 years.

This may be of value to Subaru owners too.

: No, this isn't broadcasting. Broadcasting is a transmission intended
: for reception by the general public. This is a telemetry transmission,
: a permitted one way transmission under the auxillary rules.

I can't agree with you on this Gary. Telemetry implies information being
broadcast from things such as a weather station or such,this is his email.
A little different. Also he could transmit over someone else and that is
not allowed. I think it is a good idea for his pager but I just don't
think it is totally legal. If he checked that the frequency was clear,
then used his 220 meter radio to tell his computer to send the email, that
would work.

Would you like this graffitti problem in your neighborhood? The inner cities look like Hell, because no one cares. These commercial cd-rom folks will stop advertizing in our Amateur Radio Magazines and post here for Free. Do you want all the nuts and bolts magazine ads in our news groups? Hunderds of those little ads every week over and over. Then no more ham magazines...

Many good points, Bob. But i can skip over those, and i can often tell in advance of seeing by the large number of likely-to-be flaming replies attached to it. <GRIN> I can go to their WWW site if i choose to, and who knows; they might even do something cliever like include some useful things there which could encourage one to order the whole thing. What has me much more worred is junk e-mail, things that appear, unsolicited, in our e-mail (which many of us have to pay for) from these kinds of operations, simply because we posted here. Getting alot more of those really is going to be a problem.

Almost as bad as the SALE@ALLUS on amateur packet. Does anyone really read all that junk? Oh Sure! go eat a cookie.

<MUNCH> Yeah, and it won't be quite so bad if there was enough bandwidth to support it, and clever news readers. But if you get someone who hasn't connected to their packet BBS in a week or so, and merely goes to list the summary lines of everything they haven't read since then, that alone can practically saturate the pathetic 1200 bps channels that most people use in the S.F. Bay Area. It's both a bandwidth problem nationally, and in many cases locally, aggravated by junk-box human interfaces. <SIGH> [Sorry, folks, i guess i've just had a hard day]

THE KEY TO ORGANIZING YOUR HEALTH RECORDS

"If you care about yourself and your children, you will do everything you can to know your family's medical history. It can save your life, and the lives of those who are dear to you." -- Dr. Aubry Milunsky, Director, Boston University's Center for Human Genetics (Life Magazine, March, 1995).

Your Lifetime Health Planner offers the simplest, most effective way to take charge of your health. Enter important facts about your health history, keep a record of the names of medications and their effects, document each doctor visit and diagnosis. You will have the information you need, and in the event of an emergency, so will your family.

Your Lifetime Health Planner, 198 pages in a compact, loose-leaf binder, contains a variety of sections which include "Doctor Visits," "Medications," "Family Health History," and "Doctors and Specialists." The Planner is a must for the busy executive who needs to stay organized, for seniors who are receiving care and for newborns who need a record of their health care.

Parents Magazine recommended the Planner to its readers (April, 1994) and MCI called it "a useful resource in managing your personal health records." Margie Smotherman, Coordinator, Employee Health and Wellness, Blue Shield/Blue Cross of Iowa, said: "The employees felt that these (Planners) were great tools to not only record their pertinent numbers, but to plan for doctor's visits."

To get your copy, send a check or money order for $19.95 (plus shipping and handling) to :

>Does anyone know if this is true?

Vehicles differ considerably in the "cleanliness" of their DC systems. Many produce spikes while starting, but there are also some which produce spikes after turning the ignition off, while the engine is stopping.

The degree of noise and spikes on the primary DC cables will also depend on battery size, its distance from the alternator and starter, location of ground points, battery cable size and the type of regulator and associated circuitry.

The best thing to do is to place a 'scope across the source you want to use (battery terminals, cigarette lighter plug, unused fuseholder etc.) and look for spikes or other irregularities while starting and stopping the engine, and while operating acessories such as power windows and air conditioning. Turn the headlights on and off, switch to high beam, pump the brakes etc.

If you see large problems with short term voltage regulation, one outlet to check for solutions might be a large mobile audio dealer. Some of these guys are into multi-KW mobile audio and have run the gamut of installations from the typical JVC in a Honda, to dual-alternator, triple battery systems destined for shows and contests.

From: zardoz@ornews.intel.com (Jim Garver)
Subject: Bias circuits for solid state amplifiers

I am getting ready to convert a class C solid state VHF amplifier
to class AB. I've been reading a few books including the RSGB
VHF/UHF manual and the Motorola RF power data book. My ARRL books
have little to say about this. It seems like there are a couple of
ways to do it:

Use a diode or transistor with base-collector tied together.
Mount it against the heat sink or power transistor. Series connect
it through a resistor adjusted to provide the desired current which
can either be predicted or tweaked.

Use some kind of active voltage regulator with a reference diode or
transistor mounted to the heat sink.

Are there other ways? Which is best and what problems are possible?
I thought I would use the base-collector tied transistor and adjust
the resistor for about 50-100 ma. idle current. My amp has an MRF6084
driving a pair of MRF4070's. I would use a separate bias circuit for
the 6084 and a common one for the 4070's. It pulls about 22 amps total
at 12 volts.
Thanks for any help.

From: davek@medphys.ucl.ac.uk (Dave Kirkby)
Subject: Constant impedance filters.

Does anyone know know of the configuration, or better still design-equations or
software for designing contant impedance filters. I'm looking to make a
band-pass

filter, centre =100MHz, bandwidth = 5MHz, that presents a good match to 50 Ohms over
a wide frequency range - preferably DC to 1GHz.

Most filter types reflect the unwanted signal, so present a high VSWR in the stopband. I want a filter that absorbs (hence has resistors) the unwanted signals.

The filter is required to be on the IF port of a mixer. I dont want to reflect the
image frequencies back to the mixer. Since the receiver is wide band, I cant say

what the image frequency will be - it will vary.

S T R A W B E R R Y M A N T R A R E C O R D S

To get zines distributed, Email us at the Email address below with a sample article and a description of the zine, or maybe even the whole zine, so we can make sure we want to distribute it, and if we say kuul, then send us some copies of the zine and yr in the catalog.
To get yr tapes distributed-Be good, and have nice sound quality. Send a good-sounding master tape and a master cover we can make black and white copies from to the address at the bottom. If you don't send a master cover, we'll just make one. Don't expect great artwork. John's taking drawing class.
We'll see what he can do. At least send a song list. The more you rock, the better. No Extreme-Hole Hearted Mr. Big shlock rock, please. We don't want Country or Offspring or Contemporary or R & B or Reggae or Rap tapes. So don't send them to us. If we don't like them, we put them away. Have any or all (?) of the following elements in yr music: rock, catchy rock, punk, or hardcore. Don't be lame, and, like we said, have nice sound quality.

Our royalty policy is real simple: When we distribute you, for each copy of the album you sell through us, (whether it's on vinyl or tape or cd) you get a dollar. Our royalty policy on zines is simple, too. You keep 70% of the money, we keep 30% of the money. If we (as in you and us) decide yr zine will be two dollars, we keep 60 cents for each sold zine. (60 cents just about covers postage costs. the zine department is really non-profit) The remaining $1.40 is yours! Because of this policy, we don't buy wholesale copies of zines in advance. mainly cos it's risky to us and yr zine gets more money this way.

*Online Zines: Don't wanna wait for snail mail to bring the zine to you?
Kuul! We'll Email it to you. Just send the money to the label address telling what zine you want and where we Email the zine to so you can download it-and the zine will be yours within seconds of receiving the money via a download file. Available when the catalog specifies "Online Version." Some zines are available Online only, some only by mail, some both. The royalty policies for Online Zines remain the same. (yes, postage costs don't exist when you send

online zines, but really, it's not fair to the non-online zines. Some of those zines have pictures and stuff, especially art/comic-type zines, which
would be way impossible to do online. They don't have the advantage of not paying for copying costs and postage. Just cos they have pix doesn't mean they should lose money.)

SoundClips from Strawberry Mantra Records. Download 20-45 second long samples as Wave Files from Strawberry Mantra releases.

Email the screen name below to request a SoundClip. I M P O R T A N T!!!-Must
have a sound card to play these things. If you need help, after getting yr clip, email me, i'll do what i can. Realize that mucho sound quality has to
be sacrificed to make SoundClips possible, and that SoundClips do not at ALL
represent the sound quality of Strawberry Mantra releases. If AOL said "Welcome" when you signed on, then you probably, (unless yr sound runs through that internal PC speaker that the modem noise comes through) can play
these things.

All prices include tax and shipping and handling.

If you run a little label yrself, contact us. We'll trade tapes and stuff.
We make sure the sound quality is nice on our releases. And, to smaller bands, four-track recordings are just fine. There's a lot you can do with four track recordings to make them sound really nice. We focus on the music.
That's why we give the bands the extra money, to bring out new material. It's
really money out of our pockets. But we're nice. We just want to make sure we
don't make ourselves look bad by releasing poor-quality recordings. That's all we ask. So talk to us! See ya later.
From John Mulhausen and Andrew Bales-Owners

Email SbryMantra@aol.com
Send zines, tapes and orders (cheks payable to John Mulhausen) to:
Strawberry Mantra Records
P.O. Box 701805
Tulsa, OK 74170-1805

COMING SOON
about 20 new albums are scheduled to be sent to us
The Video- a VHS tape w/ atticus finch, john, and others live. sketches, and
behind the scenes looks at kitty vamp and strawberry mantra records. probably
will cost 7 bux

Psychedelicatessen- Strawberry Mantra is putting together a compilation
that
will be sent to 14 eager radio stations. (scary) and will include at least
one
song from every band we distribute. (cept the ones on the kitty vamp
compilation, of course) and if yr on the label yr on the comp. and it's
going
to 12 radio stations who happen to be rather interested in us. scary....
zines galore. zines zines zines
tell me right now if you want to be updated. we're gonna bring out good
stuff, but give us a second, the label is as of now, about 2 weeks old.

I have gotten to the point that I need a schematic capture program for the PC or Mac. I recently bought EZ Board (or EZ-PC or something), and it does a fair job with PC boards, but it is a bear for schematics. It might be faster to draw and erase by hand.

I have used DesignWorks on the Mac and PC and found it very nice, once you get used to it, but it is a bit expensive. I may get it anyway, but I thought that I would ask here first.

What schematic capture and PC board design programs you like/dislike? Why? How much $?

: : >

I'm not gonna touch the broadcasting/telemetry issue. However, why not use procmail and a simple Korn script to have your e-mail forwarded? I have mine trim out who it is from and what the subject is and forward that to my pager. Works great. Got me out of one meeting, already. ;-) But you could just as well forward the entire thing, sans headers other than that needed From: one, if desired.

That way, you don't have to modify anything, don't have to worry about the broadcast/telemetry issue, and it won't cost anything.

Let's take it to e-mail if there isn't enough interest in the newsgroup in this, or it's thought inappropriate. I can send you a copy of my script and the relevant procmail entry in my .procmailrc file if you're interested.

Source record: 112755

Some thoughts on the simple diode regulator...

A capacitor across the diode might reduce the wideband splatter. The impedance is already low at that point so the capacitance must be huge to significantly reduce the audio frequency ripple.

At what frequency is the ripple on the bias supply? Probably below 100 Hz with typical voices. A two-tone test with widely-spaced frequencies would tend to underestimate the problem.

What is the magnitude of the bias current swings? I was naive to suggest in an earlier posting that the drive power is rectified. Some of it is dissipated without affecting the bias current.

In response to Tony K4KYO's request, the following is a message I received from Ray KV4K..... Quote'

I will type to you the exact letter as I got it from them *last week*. I would check with you about faxing it to you but this will be quicker. Retyped letter follows:

*****

Idiom Press Inc. MCI Mail 367-4633 TELEX 650-367-4633
P.O. Box 1025
Geyersville, CA 95441-1025

Dear friend,
Thank you for your inquiry about further information about the Super CMOS Keyer II as described originally in the Nov. 1990 issue of QST Magazine, and also featured in the 1992 and later editions of the Radio Amateur's Handbook.

Although we have no brochure for this product, the keyer semi-kit remains available as described, including the programmed IC, the PC board, and all on board parts. The builder must supply a speaker, an enclosure, a 100K linear taper pot, necessary input and output connectors, and a 4.5 volt supply, usually obtained from 3 - AA batteries. The kit now supplied does include the latest updated software offering all features of the original keyer plus additional features since added, as described in a later issue of QST. The kit also comes with a complete operating manual, a circuit diagram, and a parts placement guide for the PC board.

The price remains at $ 48.00 for US addresses, or US $ 50.00 for overseas orders, postage paid. California residents must also add $3.15 per kit for sales tax. Payment can be made in the form of checks or money orders, and must be drawn against US banks. We regret we cannot accept credit cards. Alternatively, US currency can be sent at the sender's risk. We can assure you it will be properly handled once received here - this is a very small business, and we are honest!

Orders are normally shipped on a once a week basis, so that may cause a small delay in receipt of the order. If you have any questions not covered by this letter, please do drop us a note, and please be sure to include a self addressed stamped envelope or IRC's.

Be sure to note our new address:

Idiom Press
P.O. Box 1025

Geyersville, CA 95441-1025

: : freqs? I have an alphanumeric pager that says it operates on 929.8625mhz.
: : Isn't that close to the cb range? It sure would be nice if I could setup
: : my own personal paging service. $20 per month is way too much for a simple
: : service like this. And no I will not be using the pager for business purposes.
: : I plan on having my email "beeped" to me.

: The only problem with this is you would be "broadcasting" and that is a
: no no in amateur radio. Great idea though!

Would it under all conditions? If the person sending was an amateur, and
the person recieving was an amateur, would this not be equal to calling
CQ?

A while back I saw a number of tone only pagers for sale (cheap) at my
favorite surplus shop. I thought it would be great for the likes of ARES
to have some way to alert everyone in a group that there was trouble
regardless as to where they were... As it was I found out just enough
about these pagers to convince me that I didn't have enough time to sort
out all the problems.

Still, I do think it would be neat.

Colin McGregor VE3ZAA

2158. Looking for low-cost PSK/DPSK demod chips...

Newsgroup: rec.radio.amateur.homebrew

>pretty constant, and if the error were really like noise it would seem like
>you could just average a lot of readings to get a more accurate fix.

In fact you *can* do just that. The SA dither is symmetrical, and if you time average long enough, you'll come to a position fix that's at least as good as the differential method. With a single reading in SA mode, your accuracy is only +/- 100 meters, and if you watch closely, succeding position plots will wander about inside that circle in a good approximation of random order. If you average enough points, you'll get a position fix down to under the +/- 10 meters promised by differential GPS. (For most receivers, this variation is most easily watched by looking at the altitude reading, which usually reads out directly in meters above MSL.)

From a military point of view, that's fine, because all they're concerned about is someone using a civilian GPS to guide a el cheapo cruise missile. By the time you time average enough readings in that case, the missile is somewhere else, so that technique doesn't pose a threat. Time averaging is useful, however, for geodesy since you can leave the receiver at the point you are surveying long enough to get a meaningful time average of the readings.

Note that the receivers themselves use time averaging. While they only update their display once a second, that update is the result of averaging many readings internally during that second. That short an averaging period, however, won't do better than +/- 100 meters. If you average over several minutes to hours, however, then you start to tighten your fix significantly.

Gary

>
>I can't agree with you on this Gary. Telemetry implies information being
>broadcast from things such as a weather station or such,this is his email.

It's still a point to point transmission in a closed network of stations,
the definition of auxillary operation, and one way transmissions are
specifically authorized for auxillary operation.

>A little different. Also he could transmit over someone else and that is
>not allowed.

Unfortunately, it is not forbidden, but that's basically irrelvant
for auxillary operations. They take place on *link* frequencies that
are usually coordinated. Like any other link, such as to a voter from
a remote repeater receiver, there is no obligation in practice to check
if the frequency is in use before transmitting because the frequency
is coordinated for the auxillary station's use. Ordinary "bulletin"
stations, such as W1AW, don't listen before transmitting either, nor
do beacons, nor do telemetry links from balloons, model craft, etc.
These types of one way transmissions are specifically authorized in
the rules, and there is no requirement to even have a receiver at
the transmission point that can monitor the transmitting frequency.

2164. SSB - why poor sound quality?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-25 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995May25.114918.64314@ucl.ac.uk>
Source record: 112672

Like many hams, I predominately send (when I had a TX) and receive SSB. However, to my mind, the sound quality is not as good as an AM transmission, using a 6KHz bandwidth for AM. Why?

I realsise the SSB bandwidth is less than half the AM one, but both contain only the 300-3000Hz frequencies. Sure AM takes up more space, but an AM TX just sends two copies of the sidebands. So SSB's more efficient use of bandwidth should not mean a redection in quality.

Perhaps other people disagree, but I'm convinced SSB does not sound as good as an amateur AM signal. Obviuosly one would not expect it to sound like a commercal AM signal, where the bandwidth exceeds the 300-3000Hz.

My thoughts as to a possible explanation are:

1) Would a typical AM signal send from very low frequencies (say 20Hz) to 3KHz, since there is no point restricting the lower ends? Since although the signal takes up less bandwidth, its most unlikely anyone else can use the space between the carrier and the lower limits of the sidebands. Perhaps then the 20Hz to 300Hz information makes the signal sound better.

2) Its very difficult to re-insert the carrier at precisely the correct frequency at the receiver. I've recently used a 2m transceiver as a tuneable IF for an HF receiver I'm biliding, The fact the tranceiver only steps in 100Hz steps definately causes poor quaility audio, but I've noticed this with VFO's too.

3) Perhaps there need to re-inser the carrier at the correct amplitude, or in the correct phase. I've never looked at the maths to say if this is true.

Any thoughts?

dave kirkby G8WRB.

2165. High intercept, low noise amp - wanted.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-25 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995May25.115811.15892@ucl.ac.uk>
Source record: 112673

I'm looking to build a lowish noise (2-4 dB) amp for about 70 or 100MHz
with a 3rd order output intercept of > +50dBm . Gain about 15dB.

Getting the nosie figure is easy. Getting the IP3 is easy, but getting the two
together is beyond me. Since I dont have access to NF measuring gear, I was
idealy looking for a circuit known to work. Failing that, any pointers on how
it might be done. I can measure IP3.

dave kirkby, G8WRB.

Those sort of things look attractive for tube amp PSU's, but I've been told they are not designed for the ripple of a 50/60Hz supply, so fail quickly if used in that service.

I dont know the specific cap being sold - its just a general warning.

Mostly this is a result of phase distortion, and massive group delay across
the passband, both on the transmit and the receive side.

I would suspect that something could be done about this by using very high
speed DSP in place of the usual phasing networks, but I haven't heard anyone
actually trying this. It could be an awful lot of fun, though.
--scott

not that cranking the ARC-5 up on AM isn't a lot of fun, too....

Here in Colorado Springs, a number of pagers have been re-crystaled to
receive the main repeater. We arranged with the repeater controllers
to set up the repeater to output the proper paging tones upon receipt of
a DTMF code. A number of Skywarn people, working with ARES, have the
pagers. They can be alerted that way. Seems to work FB. We received
the pagers through a donation, so the only cost was to re-crystal.

>>Does anyone know if this is true?

I had an experience with Regency RFH252 (XL2000) mobile radios that after
they had
aged for several years became very succeptable to noise spikes on the DC line.
Recency said that some brands of alternators had a very high, 200-500 volt,
very short
duration spike. It seems the mobile cpu reacted to this spike by putting
the worst
case of alternator whine. The radios would shift frequency, over-deviate,
under-deviate
you name it. Turn of the engine, perfection.

Maintenance free batteries are a curse in this situation. Most of these
batteries
have a higher characteristic impediance to this kind of noise. Good ol'
lead acid works
just fine.

Another factor I have found in 30 years in Avionics/Land Mobile is bad grounds.
Auto engines are poorly bonded to the vehicle chassis and therfore most DC
grounds.
Measure between the alternator frame and chassis with a heavy load (heaters,
highbeams etc.)
and observe the voltage. Improve the bonding on these grounds and a lot of
your noise will vanish.
Too mush time is spent conditioning the + side of the line without
considering the negative side.

I have embarased more that a fair number of competetiors by ripping out
their "noise filters'
and cleaning an installation with bonding straps

This is all that was posted. Do you need information?
The GE Mastar II was a building block radio that lends itself to becoming a repeater.
You need to remove the antenna switching functions and add a noise squelch switch
and an audio processor to create a repeater. If you use a commercial (re QST ads) to conversion is
simple. Just add a duplexer.

Let me know if you need more details

There were several articles on converting tube gear to solid state in one of the major ham magazines in the early 70's. The articles took the conversions a step at a time, with the approach of wiring the revised components onto the tube socket pins when possible. I even remember that the author of one of them had converted his Super Pro and claimed significant performance improvements.

I don't have these articles anymore and I'm not certain which publication they were in. If anyone has this series, I'm also interested.

Date: 22 May 1995 10:09:35 -0700
From: zardoz@ornews.intel.com (Jim Garver)
Subject: Bias circuits for solid state amplifiers

I am getting ready to convert a class C solid state VHF amplifier
to class AB. I've been reading a few books including the RSGB
VHF/UHF manual and the Motorola RF power data book. My ARRL books
have little to say about this. It seems like there are a couple of
ways to do it:

Use a diode or transistor with base-collector tied together.
Mount it against the heat sink or power transistor. Series connect
it through a resistor adjusted to provide the desired current which
can either be predicted or tweaked.

Use some kind of active voltage regulator with a reference diode or
transistor mounted to the heat sink.

Are there other ways? Which is best and what problems are possible?
I thought I would use the base-collector tied transistor and adjust
the resistor for about 50-100 ma. idle current. My amp has an MRF6084
driving a pair of MRF4070's. I would use a separate bias circuit for
the 6084 and a common one for the 4070's. It pulls about 22 amps total
at 12 volts.
Thanks for any help.

From: davek@medphys.ucl.ac.uk (Dave Kirkby)
Subject: Constant impedance filters.

Does anyone know know of the configuration, or better still design-equations or
software for designing contant impedance filters. I'm looking to make a
band-pass
filter, centre =100MHz, bandwidth = 5MHz, that presents a good match to 50 Ohms
over
a wide frequency range - preferably DC to 1GHz.

Most filter types reflect the unwanted signal, so present a high VSWR in the
stopband. I want a filter that absorbs (hence has resistors) the unwanted
signals.

The filter is required to be on the IF port of a mixer. I dont want to reflect
the
image frequencies back to the mixer. Since the receiver is wide band, I cant say

what the image frequency will be - it will vary.

To get zines distributed, Email us at the Email address below with a sample article and a description of the zine, or maybe even the whole zine, so we can make sure we want to distribute it, and if we say kuul, then send us some copies of the zine and yr in the catalog. To get yr tapes distributed-Be good, and have nice sound quality. Send a good-sounding master tape and a master cover we can make black and white copies from to the address at the bottom. If you don't send a master cover, we'll just make one. Don't expect great artwork. John's taking drawing class. We'll see what he can do. At least send a song list. The more you rock, the better. No Extreme-Hole Hearted Mr. Big shlock rock, please. We don't want Country or Offspring or Contemporary or R & B or Reggae or Rap tapes. So don't send them to us. If we don't like them, we put them away. Have any or all (?) of the following elements in yr music: rock, catchy rock, punk, or hardcore. Don't be lame, and, like we said, have nice sound quality.

Our royalty policy is real simple: When we distribute you, for each copy of the album you sell through us, (whether it's on vinyl or tape or cd) you get a dollar. Our royalty policy on zines is simple, too. You keep 70% of the money, we keep 30% of the money. If we (as in you and us) decide yr zine will be two dollars, we keep 60 cents for each sold zine. (60 cents just about covers postage costs. the zine department is really non-profit) The remaining $1.40 is yours! Because of this policy, we don't buy wholesale copies of

zines in advance. mainly cos it's risky to us and yr zine gets more money this way.

*Online Zines: Don't wanna wait for snail mail to bring the zine to you?
Kuul! We'll Email it to you. Just send the money to the label address telling
what zine you want and where we Email the zine to so you can download it-and
the zine will be yours within seconds of receiving the money via a download
file. Available when the catalog specifies "Online Version." Some zines are
available Online only, some only by mail, some both. The royalty policies for
Online Zines remain the same. (yes, postage costs don't exist when you send
online zines, but really, it's not fair to the non-online zines. Some of those zines have pictures and stuff, especially art/comic-type zines, which
would be way impossible to do online. They don't have the advantage of not paying for copying costs and postage. Just cos they have pix doesn't mean they should lose money.)

SoundClips from Strawberry Mantra Records. Download 20-45 second long samples as Wave Files from Strawberry Mantra releases.

Email the screen name below to request a SoundClip. I M P O R T A N T!!!-Must
have a sound card to play these things. If you need help, after getting yr clip, email me, i'll do what i can. Realize that mucho sound quality has to
be sacrificed to make SoundClips possible, and that SoundClips do not at ALL
represent the sound quality of Strawberry Mantra releases. If AOL said "Welcome" when you signed on, then you probably, (unless yr sound runs through that internal PC speaker that the modem noise comes through) can play
these things.

All prices include tax and shipping and handling.

If you run a little label yrself, contact us. We'll trade tapes and stuff.
We make sure the sound quality is nice on our releases. And, to smaller bands, four-track recordings are just fine. There's a lot you can do with four track recordings to make them sound really nice. We focus on the music.
That's why we give the bands the extra money, to bring out new material. It's
really money out of our pockets. But we're nice. We just want to make sure we

don't make ourselves look bad by releasing poor-quality recordings. That's all we ask. So talk to us! See ya later.
From John Mulhausen and Andrew Bales-Owners

Email SbryMantra@aol.com
Send zines, tapes and orders (cheks payable to John Mulhausen) to:
Strawberry Mantra Records
P.O. Box 701805
Tulsa, OK 74170-1805

COMING SOON
about 20 new albums are scheduled to be sent to us
The Video- a VHS tape w/ atticus finch, john, and others live. sketches, and
behind the scenes looks at kitty vamp and strawberry mantra records. probably
will cost 7 bux
Psychedelicatessen- Strawberry Mantra is putting together a compilation that
will be sent to 14 eager radio stations. (scary) and will include at least one
song from every band we distribute. (cept the ones on the kitty vamp compilation, of course) and if yr on the label yr on the comp. and it's going
to 12 radio stations who happen to be rather interested in us. scary....
zines galore. zines zines zines
tell me right now if you want to be updated. we're gonna bring out good stuff, but give us a second, the label is as of now, about 2 weeks old.

From: griff@ssd.intel.com (Thomas Griffin - x7792)
Subject: Quality of automobile DC power?

I've heard there may be large voltage spikes on the 13.8 volt DC power in an automobile due to alternator/regulator switching (or something like that). Does anyone know if this is true?

I want to operate a TNC (MFJ-1270B/TNC-2 clone, laptop computer, and a GPS receiver/Garmin GPS-45) while mobile. Assuming all of these devices are designed to operate within the normal range of automotive DC, should I have any concerns about connecting them directly to the power cable that I use with my current ham transceiver which is directly wired to the automobile battery? Or, should I build a filter circuit to protect these devices from power glitches (I'm not talking about alternator wine or ignition noise)? Any plans for specific filter designs to do this job would be greatly appreciated. Do the DC filters sold by Radio Shack and others for filtering noise for automotive sound systems also remove voltage spikes?

Thanks much in advance.

>Does anyone know if this is true?

Vehicles differ considerably in the "cleanliness" of their DC systems. Many produce spikes while starting, but there are also some which produce spikes after turning the ignition off, while the engine is stopping.

The degree of noise and spikes on the primary DC cables will also depend on battery size, its distance from the alternator and starter, location of ground points, battery cable size and the type of regulator and associated circuitry.

The best thing to do is to place a 'scope across the source you want to use (battery terminals, cigarette lighter plug, unused fuseholder etc.) and look for spikes or other irregularities while starting and stopping the engine, and while operating acessories such as power windows and air conditioning. Turn the headlights on and off, switch to high beam, pump the brakes etc.

If you see large problems with short term voltage regulation, one outlet to check for solutions might be a large mobile audio dealer. Some of these guys are into multi-KW mobile audio and have run the gamut of installations from the typical JVC in a Honda, to dual-alternator, triple battery systems destined for

shows and contests.

Don't think that's the way it works. At any one location the reading stays
pretty constant, and if the error were really like noise it would seem like
you could just average a lot of readings to get a more accurate fix. However,
like some of the others on this thread, I don't claim to know that much about
the system. In any case, as has been stated before, the reason for using LF
is more likely propagation related, especially around inland waters where
accuracy is more critical anyway.

Have a nice day.....Jay

well, i'm not familiar with the exact details -- it is no doubt someone's
State Secret -- but this doesn't resemble my experience. if you watch the
a fixed receiver, the display shows a very slowly moving position. typically
under a metre per second.

this kind of "low frequency" noise allows fairly accurate course/speed
estimates. if the noise was "high frequency" it would be almost impossible
to tell if one was moving or not via GPS alone, and indeed, any dGPS
would become quite a bit more difficult -- certainly for the current US/Canada
Coast Guard system, which, i believe, transmits corrections at something
like 50bps.

(paranoia mode on) and given the claimed purpose of SA, using low-frequency
noise makes some sense too, since it pushes the integration time up for
"precise" positions. if we want, say, a position to 10m, the present system
requires almost 1000 observations (20 minutes or so for my receiver), or
equivalently, we ignore about 9 of every 10 observations. reason: successive
positions are highly correlated -- ie, not "independent".

so paradoxically as it seems, the more noise in the signal, the more useful
the system may become in a tactical environment. (paranoia mode off)

This is why you have to arrange for the active regulator output to be
temperature compensated. Usually a silicon diode is thermally bonded to
the power transistor/heat sink and incorporated as either part of the
regulator reference voltage or in the feedback loop. The AN762 design
mentioned above does this, as I recall.

>there is such a type to avoid!

Most ordinary spray paints, such as the Krylon brand, work fine. Of course the best paints are labeled as radome paints and are properly characterized for RF use. Not cheap. The ordinary paints work nearly as well, as long as they aren't metalized. You want to avoid paints with "metalflake" because they will scatter the desired signal.

Strive for an even coat so that the dielectric constant over the face of the dish will be uniform. Painting reflectors has minimal effect on their electrical properties of interest. Painting linear elements, such as yagi elements, does have an effect on their electrical length due to the change in dielectric constant from air to that of the paint. This has a shortening effect on the elements, IE resonance will occur with slightly shorter painted elements than with bare elements since paint has a dielectric constant greater than 1.

However, you _can_ easy convert the RF section up to the 6 meter amateur
radio band, add a PTT switch for simplex, and have yourself a nice little
very-low-power 6M HT.

Maybe, but be aware that if they use the 46/49 MHz synthesizer chips, they
have ten pairs of frequencies in mask-programmed ROM. You can change the
reference crystal, but then it probably won't line up with anything in the
6M band.
I added a 2N2222 output stage on mine and boosted
the power up to almost 200 mW, which is enough for me to regularly talk
to friends across town, and sometimes do a bit of DXing in good conditions.

That sounds like a neat thing to do with something else, like a Radio Shack
49 MHz short-range HT. But if you do that, watch out about spectral purity.
At the original power level, the OEM didn't have to worry that much, but
if you amplify it, you do.

If you don't have any books handy, try http://motserv.indirect.com. This is a Motorola on-line data project. (one of the links from http://www.mot.com) Unfortunately, it is not complete. However, one of the pages is a form to fill out and get an automatic FAX of any data sheet you may need. I have not tried that specifically, however there should also be other contacts within Motorola referenced there that could help.

I have gotten data sheets for other chips in that series, it works very nicely. (Thanks, Motorola!) They also have some application notes as well. You might just spring for the databook if you're serious, and they probably have an 800 number where they can help you figure out which one to order.

There are other neat things out there, like VHF/UHF power modules, and it appears that they have some kind of retail mechanism?? (Has anyone tried that?) [No connection with Motorola -- they're just one of the better WWW sites i've found.]

>battery?

The automotive electrical system is ususlly very noisy (peaks of a few
hundred volts are common), and you must filter for that reason.
Others have already suggested where such filters can be bought.

Tapping in on the battary directly is a good approach, as the battary
is a large capacitor that will filter a lot of junk.

HOWEVER, YOU MUST INSERT FUSES IN BOTH PLUS AND GROUND LEADS.

The fuse in the positive lead has a clear reason - we all know about
the short current of an automotive battary, but the one in the ground
lead is required because if the wire between the min of the battary
and the card would fail, then the car would feed itself
using your rig, and whatever path it takes to get to ground.
These wires are NOT built for these currents.

The ARRL handbook also has some valuable suggestions on how to do this.

Geert Jan

While the U.S. Coast Guard advertises 5 meter accuracy 95% of the time,
for many periods the 3-sigma accuracy is less than 1 meter.

We routinely obtain sub-meter DGPS accuracy with
our reference stations. Among other providers, DCI also has a
1 meter service available in many areas of the U.S>

> 73,
> Jack WB3U

From the Ham Radio magazine index published Dec 1973, I found the
following:
Converting a vacuum tube receiver to solid state p. 26 Feb 69
Short circuit p. 76 Jul 69
Converting vacuum tube equipment to solid state p. 30 Aug 68
Fetrons, solid state replacemnents for tubes p. 4 Aug 72
Pentode replacement p. 70 Feb 70

I had a listing of similar stuff in QST a while back, but I don't
know where I put it. Maybe someone with access to a composite
QST index can dig it out for us. I would also like to have
the references.

A long time ago (back in the 70s) I did successfully convert a
receiver (SX-99) to all solid state. It worked like a champ
after I cured all the gremlins due to the feedback in the IF
stages. More recently I reworked an old BC band command receiver
to cover 1.5 to 2 MHz and replaced the tubes with 40673 MOSFETS
and MPF102 FETs. Works like a champ. Never did get the AGC and
product detector put into it though. Maybe someday when I have
time, but alas, no source for the 40673 - RCA quit making them.
Does anyone have a stockpile? I'm interested in about a dozen,

73,
Don W3FPR

: Those sort of things look attractive for tube amp PSU's, but I've been told they are
: not designed for the ripple of a 50/60Hz supply, so fail quickly if used in that
: service.
:
: I dont know the specific cap being sold - its just a general warning.

There were some plastic-dielectric HV caps around in Britain that had
this problem. They were designed for photoflash use - charge from DC,
and discharge in one big wallop - and they actually worked very well in
a HV PSU... for a time.

I had two, and each one lasted between one and two years before failing
internally short-circuit (resistance too low to measure).

The commonly available photoflash caps were quite compact, and thus
very attractive for PSU builders. The ones I had were much bigger,
but still broke down. One failed on standby, a few minutes after
switching on, so it was something more subtle than short-term heating
due to ripple current.

However, these aren't the same as the big old paper caps, which seem
very reliable (YMMV). There are also some very compact modern HV caps
around, which came out of TV transmitters and likewise look like a
good buy.

From: w8jitom@aol.com (W8JI Tom)
Subject: Bias circuits for solid state amplifiers

But remember that the bias current through the diode has to exceed the peak base current several times over or else the bias will wiggle around with drive. That will cause gain compression, splatter, and distortion (as many VHF/UHF operators living near people using diode biased amplifiers can attest to).

It is almost impossible to place enough standing current in a simple diode bias circuit for good linear SSB operation at power levels over a few watts. The best circuits use a temperature sensing device along with an active regulator.

If the transistor has a current gain of 10 at the operating frequency, and draws 20 amps of peak collector current, the bias diode would require at least 10 amps of standing current to remain relatively stable, since the peak base current would be 2 amps! The bias current tries to push the transistor into cutoff, so you sure don't want it to wiggle much.

This is all that was posted. Do you need information?
The GE Mastar II was a building block radio that lends itself to becoming a repeater.
You need to remove the antenna switching functions and add a noise squelch switch
and an audio processor to create a repeater. If you use a commercial (re QST ads) to conversion is
simple. Just add a duplexer.

Let me know if you need more details

From the Ham Radio magazine index published Dec 1973, I found the
following:
Converting a vacuum tube receiver to solid state p. 26 Feb 69
Short circuit p. 76 Jul 69
Converting vacuum tube equipment to solid state p. 30 Aug 68
Fetrons, solid state replacemnents for tubes p. 4 Aug 72
Pentode replacement p. 70 Feb 70

I had a listing of similar stuff in QST a while back, but I don't
know where I put it. Maybe someone with access to a composite
QST index can dig it out for us. I would also like to have
the references.

A long time ago (back in the 70s) I did successfully convert a
receiver (SX-99) to all solid state. It worked like a champ
after I cured all the gremlins due to the feedback in the IF
stages. More recently I reworked an old BC band command receiver
to cover 1.5 to 2 MHz and replaced the tubes with 40673 MOSFETS
and MPF102 FETs. Works like a champ. Never did get the AGC and
product detector put into it though. Maybe someday when I have
time, but alas, no source for the 40673 - RCA quit making them.
Does anyone have a stockpile? I'm interested in about a dozen,

73,

>>Does anyone know if this is true?

I had an experience with Regency RFH252 (XL2000) mobile radios that after
they had
aged for several years became very succeptable to noise spikes on the DC line.
Recency said that some brands of alternators had a very high, 200-500 volt,
very short
duration spike. It seems the mobile cpu reacted to this spike by putting
the worst
case of alternator whine. The radios would shift frequency, over-deviate,
under-deviate
you name it. Turn of the engine, perfection.

Maintenance free batteries are a curse in this situation. Most of these
batteries
have a higher characteristic impediance to this kind of noise. Good ol'
lead acid works
just fine.

Another factor I have found in 30 years in Avionics/Land Mobile is bad grounds.
Auto engines are poorly bonded to the vehicle chassis and therfore most DC
grounds.
Measure between the alternator frame and chassis with a heavy load (heaters,
highbeams etc.)
and observe the voltage. Improve the bonding on these grounds and a lot of
your noise will vanish.
Too mush time is spent conditioning the + side of the line without
considering the negative side.

I have embarased more that a fair number of competetiors by ripping out
their "noise filters'
and cleaning an installation with bonding straps

>you could just average a lot of readings to get a more accurate fix.

In fact you *can* do just that. The SA dither is symmetrical, and if
you time average long enough, you'll come to a position fix that's at
least as good as the differential method. With a single reading in SA
mode, your accuracy is only +/- 100 meters, and if you watch closely,
succeding position plots will wander about inside that circle in a
good approximation of random order. If you average enough points, you'll
get a position fix down to under the +/- 10 meters promised by differential
GPS. (For most receivers, this variation is most easily watched by looking
at the altitude reading, which usually reads out directly in meters
above MSL.)

From a military point of view, that's fine, because all they're concerned
about is someone using a civilian GPS to guide a el cheapo cruise missile.
By the time you time average enough readings in that case, the missile
is somewhere else, so that technique doesn't pose a threat. Time averaging
is useful, however, for geodesy since you can leave the receiver at the
point you are surveying long enough to get a meaningful time average of
the readings.

Note that the receivers themselves use time averaging. While they only
update their display once a second, that update is the result of averaging
many readings internally during that second. That short an averaging
period, however, won't do better than +/- 100 meters. If you average
over several minutes to hours, however, then you start to tighten your
fix significantly.

Gary

>broadcast from things such as a weather station or such,this is his email.

It's still a point to point transmission in a closed network of stations,
the definition of auxillary operation, and one way transmissions are
specifically authorized for auxillary operation.

>A little different. Also he could transmit over someone else and that is
>not allowed.

Unfortunately, it is not forbidden, but that's basically irrelvant
for auxillary operations. They take place on *link* frequencies that
are usually coordinated. Like any other link, such as to a voter from
a remote repeater receiver, there is no obligation in practice to check
if the frequency is in use before transmitting because the frequency
is coordinated for the auxillary station's use. Ordinary "bulletin"
stations, such as W1AW, don't listen before transmitting either, nor
do beacons, nor do telemetry links from balloons, model craft, etc.
These types of one way transmissions are specifically authorized in
the rules, and there is no requirement to even have a receiver at
the transmission point that can monitor the transmitting frequency.

I don't know about AM but I do find SSB speech quality very poor.
Note: Before digital transmission SSB used to be one way of multiplexing multiple
phone calls over a telephone cable.
>My thoughts as to a possible explanation are:
>
>1) Would a typical AM signal send from very low frequencies (say 20Hz) to 3KHz,
since
>there is no point restricting the lower ends?
I doubt it. I do like the phase distortion theory that is presented in a reply
to this article. Traditionaly not much attention has been paid to the phase
distortion introduced by filters, the concern has generally been on magnitude
response. Phase is very important especially when using digital transmission
modes (QAM, PSK)
>
>2) Its very difficult to re-insert the carrier at precisely the correct frequency at

>3) Perhaps there need to re-inser the carrier at the correct amplitude, or
>in the correct phase. I've never looked at the maths to say if this is true.
>
Amplitude doesn't matter, except in obtaining proper performance of the
demoduator, i.e. too much/too little carrier power. In my text books
they always perform synchronous detection, i.e. the phase of the carrier
at the receiver is identical to that at the transmitter. If the phase
is not identical then when demodulation takes place the amplitude of
the demodulated signal is weighted by the cos/sin of the phase error.
This requires a phase tracking loop (& frequency) which greatly increases
the complexity of the receiver as opposed to a simple VFO. I have never
understood how we get rid of the "phase error" with our equipment - unless
it is done by "manually tuning in" the signal. Anyway, a resolution of
better than 10 Hz is needed to get satisfactory performance (unless using
a channelized system, e.g. like the 5 kHz steps on the 2 mtr band).

Any thoughts on the phase problem ?

Bill Kirkland

2197. Component Values for Parasitic Suppressors?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-26 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3q4sns$e0e@misc1.microserve.net>
Source record: 112700

One of the projects I need to tackle soon will be to tame a parasitic oscillation in an old Gonset GSB-201 KW HF amplifier. This job was started a number of years ago, but I moved before completing the work and have not been active again until now. Any advice or comments will be appreciated.

To begin, the amplifier uses (4) 811A's in GG and the oscillation was (roughly) measured with a scope as a low-level parasitic at approximately 60-65 MHz. It is present on every band, regardless of tune or load capacitor settings. The amplifier circuit includes a (factory) non-adjustable neutralizing circuit and a parasitic suppressor at the plate lead of each tube. Grids float to allow application of DC bias, but are bypassed for RF directly at the tube sockets. I have added a small-value disc cap at each grid pin, but changes to the grid circuit do not seem to affect the parasitic to any significant degree.

This brings me to the subject of parasitic suppressors . . .

The upper frequency range of 811A's does not extend nearly as far as 3-500Z's and other later-style tubes. The upper limit for full ratings is 60 MHz, which leads me to believe that parasitics would be unlikely to occur (or to need suppression) above perhaps 70 MHz or so.

For the sake of argument, let's say that the typical suppressor in an amplifier of this type consists of 6 turns at a diameter of 0.3", and with a total length of 0.5". This provides a coil with an inductance of approximately 0.13 uH, which is wound on a 100 ohm resistor. In comparing the effect of this parallel L/R circuit at the desired and undesired frequencies, I arrive at the folowing numbers:

30 MHz 70 MHz
XL 24.0 ohms 56.1 ohms
Z 23.4 ohms 48.9 ohms

From these results, I have the following questions:

1. Given the potential for high circulating currents on the higher bands, the impedance of the network at 30 MHz seems excessive. Why is this not more of a concern in high power amplifiers?

2. The impedance of the network at 70 MHz is only a little more than twice the value at 30 MHz. If the impedance at 30 MHz does not impair the efficiency of the amplifier to a significant

degree, how can this modest increase be effective in suppressing the parasitic?

3. It has previously been suggested on this newsgroup that to resolve stubborn parasitics, a capacitor can be placed in parallel with the inductor, with the pair tuned to the undesired frequency. Given my assumption that 811A's are unlikely to oscillate above 70 MHz, should this perhaps be a routine technique for these particular tubes?

4. Again, with a capacitor in parallel, should the resistor be removed or increased in value, in order to improve the Q of the suppressor? Wouldn't this improve its rejection of the parasitic, while minimizing its effect on signals at the desired frequencies?

5. Finally, regardless of whether the resistor is removed, what type of series capacitor should be used (disc, sm etc.)? My calculations of the suppressor as an independent network indicate that resonating the coil at 60 MHz would require a 55 pf capacitor.

Thanks for taking time to read this. Any and all input on this subject will be appreciated.

73,

Jack WB3U

>Bill Kirkland

I've had the same thoughts about group delay distortion through the crystal filters used for SSB. In Saben's book on SSB he mentions that group delay distortion can result in distorted audio since speech is made up of many frequency components, if the individual frequency components do not arrive in time synch, due to group delay distortion, the result is distorted audio. That's roughly the explaination from memory. I've been wanting to get my hands on some crystal filters to measure group delay through them to get a feel for the effect. Anybody done these measurements already so I don't have to re-invent the wheel? The real question is whether or not the group delay distortion problem is on the order of the same magnitude of the non-linearities in the circuit. A friend and I have had this discussion. He thinks the circuit non-linearities are greater but I'm still waiting to be convinced.

Thanks for the information, I thought that they were getting a lot trickier than that. don't know that I'll ever have occasion to make use of it, but its always better to know more than you need. I don't as yet have a GPS xcvr, but it would be nice. (just don't have a good enough need).

Have a nice day....Jay

You got it. And, this is pretty much going to happen if you use any
sort of infinite impulse response filter. Note that also the phase-shift
networks on the transmit side do not have an even phase response, and they
are also responsible for a lot of the distortion.

>I've been wanting to get my hands on some crystal filters to
>measure group delay through them to get a feel for the effect. Anybody
>done these measurements already so I don't have to re-invent the
>wheel?

Yes, there is a bunch of stuff in the IRE journals in the forties and
fifties on the subject, mostly talking about filters for AM listening
but which still should be useful. Remember that the group delay at
the edges of the passband is directly related to the slope of the
cutoff. If you think the crystal filters are bad, you should just
listen to something like the Collins receivers with the mechanical
filters. They do an amazing job of cutting out interference, but
the group delay is awful. Incidentally, has anyone out there tried
building an all-pass network on the audio output to compensate for
somet of this?

The real question is whether or not the group delay distortion
>problem is on the order of the same magnitude of the non-linearities
>in the circuit. A friend and I have had this discussion. He thinks the
>circuit non-linearities are greater but I'm still waiting to be
>convinced.

The nonlinearities are significant. The group delay distortion is
also significant. Which one is dominant depends on your transmitter
and your receiver, but with good equipment, the group delay is dominant.

Tight filters are good things in that they reduce interference, but they are bad things in that they induce phase distortion. Likewise the phasing networks on the transmitter are essential to get proper modulation, but building good ones is expensive and building perfect ones is impossible.

If you want to do a measurement on a crystal filter yourself, just get a colorburst crystal from your local TV supplier, a signal generator, and a scope, and rig it up as a series resonant filter. (Yes, I know that isn't an optimum configuration, but it's easy to do and it works well enough for a demonstration).

Those wishing to pursue the "whys" of the problem of poor fidelity in SSB voice transmission might want to consider that in FM stereo broadcasting the L-R audio is broadcast as a DSBSC (double sideband suppressed carrier) signal centered at 38 kHz. In the receiver, this DSBSC signal is demodulated (using the 19 kHz pilot tone as a frequency and phase reference) and the resulting L-R audio combined with the L+R audio from the main channel, resulting in separate L & R signals. The FCC technical standard for phase coherence between the main channel and stereophonic subchannel is +/- 3 degrees (which is satisfied by achieving a stereo separation of 29.7 dB) (Paragraph 73.322(m) of Part 73).

The key differences are (a) a DSB signal requires no filtering, and (b) in FM broadcasting a 19 kHz pilot tone is transmitted which must have a frequency accuracy of +/- 2 Hz. In addition, there is a phase-coherency requirement which is "built in" to the transmitter, and requires careful attention throughout the entire audio chain since the FCC specification applies to the entire path from microphone input to transmitter output.

As far as determining which of the two components (filter group delay or TX to RX phase incoherency) is the biggest culprit, that might be difficult to pin down. I would be tempted to try DSB with a SSB transmitter by perhaps bypassing the filter and doing an "empirical audio quality comparison." This would take filter group delay out of consideration. Trying to come up with some kind of phase-coherent detection in your average ham rig would, I suspect, be a much nastier problem to attack.

About 3 years ago we did a study on this problem as related to the use of VHF/UHF receivers for signal collection. We examined a number of different filter types including Gaussian, 6 and 12 dB transistional, Chebychev, Elliptic, and Equiripple Phase 0.5 degree. The last type had the best combination of group delay and ringdown characteristics (the latter being of most importance when dealing with pulse signals).

The tradeoff for the more common filter architectures is that the better the group delay and ringdown, the worse the shape factor. The Chebychev is nice and sharp but is by far the worst in terms of group delay. Since USB and LSB filters tend to have a very sharp slope on the side adjacent to the center frequency (for unwanted sideband rejection) I'm confident that their group delay characteristics are horrendous.

BTW, regarding the "tradeoff" noted above, in applications where a low ultimate rejection (<50 dB) and high insertion loss can be tolerated, a SAW filter is the best choice; near-vertical skirts and nice, flat group delay.

Of course, none of this answers the question of "what's doing the most damage".............

The distortion from unequal group delay affects modems (which is one
reason why they have adaptive phase equalizers) but is not audible
by ear when listening to speech. What *is* audible vis a vis filters
is amplitude ripple, at least if it is bad enough.

The SSB filters the phone companies used in the old analog FDM
systems had flat amplitude response, and lots of phase distortion,
and they sounded much better than anything you hear on the air,
except for SWBC station point to point SSB links, which sound as good
as AM on a good receiver.

I suspect the main culprit is the nonlinear distortion
in the average SSB transmitter.

You can also do this with digital (FIR) filters. I have listened
to such FIR filters and they don't sound any better than the old
phone company analog filters, because group delay distortion is generally
inaudible. They are, of course, kinder and gentler to modems.

I once built an adjustable audio all pass network, where I could
adjust the center frequency from 20 Hz to 20 kHz. with a pot.
I put music thru it (from a decent stereo system) and listened
to it with high quality headphones. I A/B'ed the music with and
without the network at various frequency settings, and was never
able to detect any difference. I took it into work here and hooked
in up to a function generator and tried square waves, triangle waves,
etc. No audible effect. On the other hand, the waveform, as
displayed on a scope went totally nuts, as you'd expect.
I let some of the guys here try it too and they couldn't hear any
difference either.

The all pass in question was a first order type:

```
s-a
F(s) = -------
s+a
```

The conclusion is that you can't hear delay distortion. I later
found out about a JAES paper that essentially agreed with my findings.

Do you mean that AM sounds better when you listen to a commercial broadcaster using a
modern receiver with a 6 KHz xtal filter, or that Amateur AM in the old days sounded
better?
I'm asking this because I agree with you, but only as it relates to the old rigs. I think
the
difference occurs for two reasons. First, older transmitters (AM) used audio filtering to
rolloff the audio outside the 300 - 3000 range. In most cases, the rolloff was *very* slow
and still had significant energy outside this band. Second, older AM receivers had a
passband much broader than 6 KHz, and with kinder, gentler rolloff than today's filters.
I can still remember how bad they sounded on AM, relatively speaking, when the crystal
filter (usually only two crystals) was activated. Try this sometime with an SX-28 and
you'll see what I mean.

>Perhaps other people disagree, but I'm convinced SSB does not sound as good as an
>amateur AM signal. Obviuosly one would not expect it to sound like a commercal AM

To say that it doesn't sound as good is an understatement. Personally, I find it extremely
tiring, which is just one more reason I work more CW than 'phone <g>.

>My thoughts as to a possible explanation are:
>
>1) <snip> Perhaps then the 20Hz to 300Hz information makes the signal sound better.

Yep.

>the receiver. <snip>
>
>3) Perhaps there need to re-inser the carrier at the correct amplitude, or
>in the correct phase. I've never looked at the maths to say if this is true.

I don't think 2) and 3) have a significant impact. As evidence of this, I recall several
friends of mine in the 60's who converted their ARC-5 transmitters to DSB and who
achieved very respectable carrier suppression. Using a receiver at the time which
couldn't even keep 100 Hz accuracy (let alone 10 Hz), I can tell you that the fidelity
of their signals was *almost* as good as standard AM.

Subject: Component Values for Parasitic Suppressors?

Jack,

Some of this will be similar to something I posted under a *SB-220 heading in equipment newsgroup.

>To begin, the amplifier uses (4) 811A's in GG and the oscillation was (roughly) measured with a scope as a low-level parasitic at approximately 60-65 MHz. It is present on every band, regardless of tune or load capacitor settings.<

That is typical for tubes with long grid leads like 811's, 572's, 3-1000's, 3CX1200's , and so on.

>The amplifier circuit includes a (factory) non-adjustable neutralizing circuit and a parasitic suppressor at the plate lead of each tube. Grids float to allow application of DC bias, but are bypassed for RF directly
at the tube sockets. I have added a small-value disc cap at each grid pin, but changes to the grid circuit do not seem to affect the parasitic to any significant degree.<

Keeping the grid inductance as low as possible moves the parasitic up as high as possible in freq. The best idea is to ground the grids directly, and if they must float to use a very low inductance cap that has negligible reactance at the lowest operating frequency from each grid pin to ground. I would use a small monolithic or multi-layer chip of at least .01 mFd with "zero" lead length. It is critical that the caps series resonant freq be close to or above the tube's self neutralizing freq.

>This brings me to the subject of parasitic suppressors . . .<

>The upper frequency range of 811A's does not extend nearly as far as 3-500Z's and other later-style tubes. The upper limit for full ratings is 60 MHz, which leads me to believe that parasitics would be unlikely to occur (or to need suppression) above perhaps 70 MHz or so.<

The oscillation occurs, IF it occurs, around or just above the maximum useful frequency of the tube.

>For the sake of argument, let's say that the typical suppressor in an amplifier of this type consists of 6 turns at a diameter of 0.3", and with a total length of 0.5". This provides a coil with an inductance of approximately 0.13 uH, which is wound on a

100 ohm resistor. In comparing the effect of this parallel L/R
circuit at the desired and undesired frequencies, I arrive at the
folowing numbers:

30 MHz 70 MHz
XL 24.0 ohms 56.1 ohms
Z 23.4 ohms 48.9 ohms

From these results, I have the following questions:<

>1. Given the potential for high circulating currents on the
higher bands, the impedance of the network at 30 MHz seems
excessive. Why is this not more of a concern in high power
amplifiers?<

It is a huge concern. The anode capacitance of the tube usually
forms the bulk of the input capacitance of the tank circuit. Very high
current appears across the parasitic suppressor at ten and fifteen
meters, since it is in the path of the tank circuit circulating currents.
The ideal suppressor coil would have a very high Z at the frequency
of the parasitic, and no appreciable R or Z at the operating
frequency to prevent a loss of harmonic suppression and tank Q.

>2. The impedance of the network at 70 MHz is only a little more
than twice the value at 30 MHz. If the impedance at 30 MHz does
not impair the efficiency of the amplifier to a significant
degree, how can this modest increase be effective in suppressing
the parasitic?<

That is why the tubes mentioned above are often such headaches to
stabilize. A failure to do an analysis (like you did) can lead to some
erroneous efforts to remove parasitics, and cause some real voodoo
cures. You've analyzed and pointed out the real problem correctly
Jack, and without using gongs or sudden burst of unexplained
energy! That's something self proclaimed gurus often fail to do.
Great job, Jack. That should have been done in QST.

>3. It has previously been suggested on this newsgroup that to
resolve stubborn parasitics, a capacitor can be placed in
parallel with the inductor, with the pair tuned to the undesired
frequency. Given my assumption that 811A's are unlikely to
oscillate above 70 MHz, should this perhaps be a routine
technique for these particular tubes?<

I have a patent applied for the first method I am outlining. But two
methods can work very well.

The first is to place a capacitor in series with an inductor and series
tune the circuit at the parasitic frequency. The resistor goes in series
with this combination, and the series RLC combination goes across
a slightly larger parasitic coil in series with the anode lead. This
inductance can even be "built into" the resistor by using a
conventional carbon film or metal film resistor. The capacitor series

resonates the resistor's VHF path, and the high series reactance at the operating frequency prevents the resistor from dissipating much fundamental power. This offers a broader suppression bandwidth and improved parasitic suppressor performance.

A word of caution, cut a resistor open or inspect it on a network analyzer before using it. Most carbon and metal film resistors use a spiral winding of resistive material that decreases the effectiveness of the suppressor unless the unwanted reactance is series tuned out by a small fixed capacitor.

The second is to place a capacitor across the coil in a conventional suppressor, that will allow the use of less turns and still have a very high impedance at the parasitic frequency. This method is best if you are operating very close to the frequency of the parasitic, especially if used in conjunction with the series RLC dissipating circuit mentioned above.

>4. Again, with a capacitor in parallel, should the resistor be removed or increased in value, in order to improve the Q of the suppressor?<

No, actually the inductance should be decreased! Remember the impedance goes very high at the parallel resonant frequency, so the L doesn't need to be nearly as big. The R is determined by the ratio of the anode circuit reactance to the series R value. A higher value R works better in high impedance VHF anode paths.

> Wouldn't this improve its rejection of the parasitic, while minimizing its effect on signals at the desired frequencies?<

Yes, all of this does.

>5. Finally, regardless of whether the resistor is removed, what type of series capacitor should be used (disc, sm, etc.)? My calculations of the suppressor as an independent network indicate that resonating the coil at 60 MHz would require a 55 pF capacitor.<

Not much current or voltage appears across the suppressor if it is doing it's job and properly designed. A 500 volt DM 05 case size is generally large enough. The size would depend on the exact circuit used. The key is to make the resistor entirely dominate the anode load at the parasitic frequency, and the path to appear as a very low impedance at the highest operating frequency. The resistor can't be removed though.

This has always been my biggest problem with the use of nichrome. The nichrome coil is in the LF signal path (the coil) and has the largest effect on the signal at the operating frequency. The resistor is the path for the VHF currents and that doesn't change. Nichrome primarily lowers the Q at HF, and hardly changes it at all at UHF! Exactly the opposite of some popular claims.

Bingo! It's the frequency translation error that gets you. If you have
any frequency translation error, the harmonic relationships of the
speech (or music) components no longer line up. So instead of nice
harmonies, you have dissonance which is very grating to the ear.
It's like listening to a musical instrument that isn't tuned on a
well tempered scale.

The group delay of the crystal filters is one good reason; it intuitively makes sense to me. Other reasons: SSB transmitters may be less concerned with low audio distortion because they know a lot of the distortion components will end up filtered out. This is true of harmonic components, of course, but still leaves various intermodulation components audible.

Also, I'll bet many of the old AM transmitters did not filter the speech bandwidth quite as sharply as a modern filter-type SSB rig; thus a little more lows and highs creep through, despite the nominal frequency response of 300-3000 Hz.

It's a real kick to use my Campbell R2 receiver design -- the Jan. 93 QST direct conversion RX that phases out the other sideband. All the audio is low distortion -- and if you switch out the audio filters, you have a nice broad response that gently rolls off outside the speech bandwidth, making for very good zero-beat broadcast reception, and a reasonably objective evaluation tool for audioquality evaluation. I can't wait to hook up the companion T2 phasing exciter -- I could run it on AM without filters and go true hi-fi :-)

>reason why they have adaptive phase equalizers) but is not audible
>by ear when listening to speech. What *is* audible vis a vis filters
>is amplitude ripple, at least if it is bad enough.

Group delay is audible if it is bad enough. This is the *click-boom*
effect that plagues some loudspeaker designs, IE the path for the
high frequency components is a different length than the path for low
frequency components with the high frequency components typically
arriving first. This causes the "click" of a percussive drum strike
to arrive before the "boom" of the drum. Instead of kaboom, you hear
click <pause> boom. It's less noticable on speech, but it's there,
and adds to listener fatigue. However, the group delay through an
RF filter is so small compared to the time of an *audio* cycle
as to be insignificant. You can't hear it.

The much more serious effect for SSB is frequency mistranslation.
This causes harmonic dissonance, and the ear is very sensitive
to that. For example, a speech component that has a 16 Hz, 32 Hz,
and 64 Hz harmony, will be dissonant if the frequency translation
error is 10 Hz so that you now have the sequence 26 Hz, 42 Hz,
and 74 Hz. The tones are no longer harmonically related, and
sound dissonant to the ear. This is still noticable to the ear
at higher frequencies where the error is a smaller percentage.
You have to get the error down under a couple of Hertz for the
ear not to detect it. Otherwise, the harmonic "beat" will cause
a warble that's noticable to the ear. An example is a guitar that
is slightly out of tune, you can notice the beat even though it's
at a frequency below the audible range.

>I suspect the main culprit is the nonlinear distortion
>in the average SSB transmitter.

This is certainly a factor with amateur gear. The frequency
response of the entire chain, microphone, speech amp, compressor,

DSB generator, filter, and linear amplifiers, all have an effect on speech quality. And similarly, all the stages of the receiver also contribute. Aside from frequency mistranslation, the most striking effects occur in the audio stages at both ends. For some reason, amateur manufacturers seem to think 10% THD is a *desirable* specification for the audio sections of their radios.

One of the best things you can do to improve the fidelity of your radio is to improve and flatten the response of your audio stages. A receiver audio stage that has flat response from 20 Hz to 20,000 Hz, and that has 0.01% THD, will sound worlds better than one that is constricted and distorted, and will lead to *much* less listener fatigue. The same can be said for the transmitter audio stages. In this regard, the use of audio filters on receivers should strongly be discouraged. The group delay through such filters *is* significant compared to an audio cycle, and *is* audible. Do your selective filtering at RF where the group delay is an insignificant portion of an audio cycle.

Gary

Subject: Component Values for Parasitic Suppressors?

One of the projects I need to tackle soon will be to tame a parasitic oscillation in an old Gonset GSB-201 KW HF amplifier. This job was started a number of years ago, but I moved before completing the work and have not been active again until now. Any advice or comments will be appreciated.

To begin, the amplifier uses (4) 811A's in GG and the oscillation was (roughly) measured with a scope as a low-level parasitic at approximately 60-65 MHz. It is present on every band, regardless of tune or load capacitor settings. The amplifier circuit includes a (factory) non-adjustable neutralizing circuit and a parasitic suppressor at the plate lead of each tube. Grids float to allow application of DC bias, but are bypassed for RF directly at the tube sockets. I have added a small-value disc cap at each grid pin, but changes to the grid circuit do not seem to affect the parasitic to any significant degree.

This brings me to the subject of parasitic suppressors . . .

The upper frequency range of 811A's does not extend nearly as far as 3-500Z's and other later-style tubes. The upper limit for full ratings is 60 MHz, which leads me to believe that parasitics would be unlikely to occur (or to need suppression) above perhaps 70 MHz or so.

For the sake of argument, let's say that the typical suppressor in an amplifier of this type consists of 6 turns at a diameter of 0.3", and with a total length of 0.5". This provides a coil with an inductance of approximately 0.13 uH, which is wound on a 100 ohm resistor. In comparing the effect of this parallel L/R circuit at the desired and undesired frequencies, I arrive at the folowing numbers:

30 MHz 70 MHz
XL 24.0 ohms 56.1 ohms
Z 23.4 ohms 48.9 ohms

From these results, I have the following questions:

1. Given the potential for high circulating currents on the higher bands, the impedance of the network at 30 MHz seems excessive. Why is this not more of a concern in high power amplifiers?

2. The impedance of the network at 70 MHz is only a little more than twice the value at 30 MHz. If the impedance at 30 MHz does not impair the efficiency of the amplifier to a significant degree, how can this modest increase be effective in suppressing the parasitic?

3. It has previously been suggested on this newsgroup that to resolve stubborn parasitics, a capacitor can be placed in parallel with the inductor, with the pair tuned to the undesired frequency. Given my assumption that 811A's are unlikely to oscillate above 70 MHz, should this perhaps be a routine technique for these particular tubes?

4. Again, with a capacitor in parallel, should the resistor be removed or increased in value, in order to improve the Q of the suppressor? Wouldn't this improve its rejection of the parasitic, while minimizing its effect on signals at the desired frequencies?

5. Finally, regardless of whether the resistor is removed, what type of series capacitor should be used (disc, sm etc.)? My calculations of the suppressor as an independent network indicate that resonating the coil at 60 MHz would require a 55 pf capacitor.

Thanks for taking time to read this. Any and all input on this subject will be appreciated.

73,

Jack WB3U

Dave,

You can FTP a freeware Preamp program for DOS from oak.oakland.edu located under /SimTel/msdos/hamradio under file KD9JQ_95.ZIP. You need pkunzip (Ver 204G) to unzip.

I included a number of options you might like.

Cheers...Chuck

Most ordinary spray paints, such as the Krylon brand, work fine. Of course the best paints are labeled as radome paints and are properly characterized for RF use. Not cheap. The ordinary paints work nearly as well, as long as they aren't metalized. You want to avoid paints with "metalflake" because they will scatter the desired signal.

Strive for an even coat so that the dielectric constant over the face of the dish will be uniform. Painting reflectors has minimal effect on their electrical properties of interest. Painting linear elements, such as yagi elements, does have an effect on their electrical length due to the change in dielectric constant from air to that of the paint. This has a shortening effect on the elements, IE resonance will occur with slightly shorter painted elements than with bare elements since paint has a dielectric constant greater than 1.

From: w8jitom@aol.com (W8JI Tom)
Subject: Component Values for Parasitic Suppressors?

Subject: Component Values for Parasitic Suppressors?

Jack,

Some of this will be similar to something I posted under a *SB-220 heading in equipment newsgroup.

>To begin, the amplifier uses (4) 811A's in GG and the oscillation was (roughly) measured with a scope as a low-level parasitic at approximately 60-65 MHz. It is present on every band, regardless of tune or load capacitor settings.<

That is typical for tubes with long grid leads like 811's, 572's, 3-1000's, 3CX1200's , and so on.

>The amplifier circuit includes a (factory) non-adjustable neutralizing circuit and a parasitic suppressor at the plate lead of each tube. Grids float to allow application of DC bias, but are bypassed for RF directly
at the tube sockets. I have added a small-value disc cap at each grid pin, but changes to the grid circuit do not seem to affect the parasitic to any significant degree.<

Keeping the grid inductance as low as possible moves the parasitic up as high as possible in freq. The best idea is to ground the grids directly, and if they must float to use a very low inductance cap that has negligible reactance at the lowest operating frequency from each grid pin to ground. I would use a small monolithic or multi-layer chip of at least .01 mFd with "zero" lead length. It is critical that the caps series resonant freq be close to or above the tube's self neutralizing freq.

>This brings me to the subject of parasitic suppressors . . .<

>The upper frequency range of 811A's does not extend nearly as far as 3-500Z's and other later-style tubes. The upper limit for full ratings is 60 MHz, which leads me to believe that parasitics would be unlikely to occur (or to need suppression) above perhaps 70 MHz or so.<

The oscillation occurs, IF it occurs, around or just above the maximum useful frequency of the tube.

>For the sake of argument, let's say that the typical suppressor in an amplifier of this type consists of 6 turns at a diameter of 0.3", and with a total length of 0.5". This provides a coil with an inductance of approximately 0.13 uH, which is wound on a 100 ohm resistor. In comparing the effect of this parallel L/R circuit at the desired and undesired frequencies, I arrive at the folowing numbers:

30 MHz 70 MHz
XL 24.0 ohms 56.1 ohms
Z 23.4 ohms 48.9 ohms

From these results, I have the following questions:<

>1. Given the potential for high circulating currents on the
higher bands, the impedance of the network at 30 MHz seems
excessive. Why is this not more of a concern in high power
amplifiers?<

It is a huge concern. The anode capacitance of the tube usually forms the bulk of the input capacitance of the tank circuit. Very high current appears across the parasitic suppressor at ten and fifteen meters, since it is in the path of the tank circuit circulating currents. The ideal suppressor coil would have a very high Z at the frequency of the parasitic, and no appreciable R or Z at the operating frequency to prevent a loss of harmonic suppression and tank Q.

>2. The impedance of the network at 70 MHz is only a little more
than twice the value at 30 MHz. If the impedance at 30 MHz does
not impair the efficiency of the amplifier to a significant
degree, how can this modest increase be effective in suppressing
the parasitic?<

That is why the tubes mentioned above are often such headaches to stabilize. A failure to do an analysis (like you did) can lead to some erroneous efforts to remove parasitics, and cause some real voodoo cures. You've analyzed and pointed out the real problem correctly Jack, and without using gongs or sudden burst of unexplained energy! That's something self proclaimed gurus often fail to do. Great job, Jack. That should have been done in QST.

>3. It has previously been suggested on this newsgroup that to
resolve stubborn parasitics, a capacitor can be placed in
parallel with the inductor, with the pair tuned to the undesired
frequency. Given my assumption that 811A's are unlikely to
oscillate above 70 MHz, should this perhaps be a routine
technique for these particular tubes?<

I have a patent applied for the first method I am outlining. But two methods can work very well.

The first is to place a capacitor in series with an inductor and series tune the circuit at the parasitic frequency. The resistor goes in series with this combination, and the series RLC combination goes across a slightly larger parasitic coil in series with the anode lead. This inductance can even be "built into" the resistor by using a conventional carbon film or metal film resistor. The capacitor series resonates the resistor's VHF path, and the high series reactance at the operating frequency prevents the resistor from dissipating much fundamental power. This offers a broader suppression bandwidth and improved parasitic suppressor performance.

A word of caution, cut a resistor open or inspect it on a network analyzer before using it. Most carbon and metal film resistors use a spiral winding of resistive material that decreases the effectiveness of the suppressor unless the unwanted reactance is series tuned out by a small fixed capacitor.

The second is to place a capacitor across the coil in a conventional suppressor, that will allow the use of less turns and still have a very high impedance at the parasitic frequency. This method is best if you are operating very close to the frequency of the parasitic, especially if used in conjunction with the series RLC dissipating circuit mentioned above.

>4. Again, with a capacitor in parallel, should the resistor be removed or increased in value, in order to improve the Q of the suppressor?<

No, actually the inductance should be decreased! Remember the impedance goes very high at the parallel resonant frequency, so the L doesn't need to be nearly as big. The R is determined by the ratio of the anode circuit reactance to the series R value. A higher value R works better in high impedance VHF anode paths.

> Wouldn't this improve its rejection of the parasitic, while minimizing its effect on signals at the desired frequencies?<

Yes, all of this does.

>5. Finally, regardless of whether the resistor is removed, what type of series capacitor should be used (disc, sm, etc.)? My calculations of the suppressor as an independent network indicate that resonating the coil at 60 MHz would require a 55 pF capacitor.<

Not much current or voltage appears across the suppressor if it is doing it's job and properly designed. A 500 volt DM 05 case size is generally large enough. The size would depend on the exact circuit used. The key is to make the resistor entirely dominate the anode load at the parasitic frequency, and the path to appear as a very low impedance at the highest operating frequency. The resistor can't be removed though.

This has always been my biggest problem with the use of nichrome. The nichrome coil is in the LF signal path (the coil) and has the largest effect on the signal at the operating frequency. The resistor is the path for the VHF currents and that doesn't change. Nichrome primarily lowers the Q at HF, and hardly changes it at all at UHF! Exactly the opposite of some popular claims.

73, Tom W8JI

In response to Tony K4KYO's request, the following is a message I
received from Ray KV4K..... Quote'

I will type to you the exact letter as I got it from them *last week*.
I would check with you about faxing it to you but this will be quicker.
Retyped letter follows:

*****

Idiom Press Inc. MCI Mail 367-4633 TELEX 650-367-4633
P.O. Box 1025
Geyersville, CA 95441-1025

Dear friend,
Thank you for your inquiry about further information about the Super
CMOS Keyer II as described originally in the Nov. 1990 issue of QST
Magazine, and also featured in the 1992 and later editions of the Radio
Amateur's Handbook.

Although we have no brochure for this product, the keyer semi-kit
remains available as described, including the programmed IC, the PC
board, and all on board parts. The builder must supply a speaker, an
enclosure, a 100K linear taper pot, necessary input and output
connectors, and a 4.5 volt supply, usually obtained from 3 - AA
batteries. The kit now supplied does include the latest updated
software offering all features of the original keyer plus additional
features since added, as described in a later issue of QST. The kit
also comes with a complete operating manual, a circuit diagram, and a
parts placement guide for the PC board.

The price remains at $ 48.00 for US addresses, or US $ 50.00 for
overseas orders, postage paid. California residents must also add
$3.15 per kit for sales tax. Payment can be made in the form of checks
or money orders, and must be drawn against US banks. We regret we
cannot accept credit cards. Alternatively, US currency can be sent at
the sender's risk. We can assure you it will be properly handled once
received here - this is a very small business, and we are honest!

Orders are normally shipped on a once a week basis, so that may cause a
small delay in receipt of the order. If you have any questions not
covered by this letter, please do drop us a note, and please be sure
to include a self addressed stamped envelope or IRC's.

Be sure to note our new address:

Idiom Press
P.O. Box 1025
Geyersville, CA 95441-1025

From: jackl@pinetree.microserve.com (WB3U)
Subject: Component Values for Parasitic Suppressors?

One of the projects I need to tackle soon will be to tame a parasitic oscillation in an old Gonset GSB-201 KW HF amplifier. This job was started a number of years ago, but I moved before completing the work and have not been active again until now. Any advice or comments will be appreciated.

To begin, the amplifier uses (4) 811A's in GG and the oscillation was (roughly) measured with a scope as a low-level parasitic at approximately 60-65 MHz. It is present on every band, regardless of tune or load capacitor settings. The amplifier circuit includes a (factory) non-adjustable neutralizing circuit and a parasitic suppressor at the plate lead of each tube. Grids float to allow application of DC bias, but are bypassed for RF directly at the tube sockets. I have added a small-value disc cap at each grid pin, but changes to the grid circuit do not seem to affect the parasitic to any significant degree.

This brings me to the subject of parasitic suppressors . . .

The upper frequency range of 811A's does not extend nearly as far as 3-500Z's and other later-style tubes. The upper limit for full ratings is 60 MHz, which leads me to believe that parasitics would be unlikely to occur (or to need suppression) above perhaps 70 MHz or so.

For the sake of argument, let's say that the typical suppressor in an amplifier of this type consists of 6 turns at a diameter of 0.3", and with a total length of 0.5". This provides a coil with an inductance of approximately 0.13 uH, which is wound on a 100 ohm resistor. In comparing the effect of this parallel L/R circuit at the desired and undesired frequencies, I arrive at the folowing numbers:

30 MHz 70 MHz
XL 24.0 ohms 56.1 ohms
Z 23.4 ohms 48.9 ohms

From these results, I have the following questions:

1. Given the potential for high circulating currents on the higher bands, the impedance of the network at 30 MHz seems excessive. Why is this not more of a concern in high power amplifiers?

2. The impedance of the network at 70 MHz is only a little more
than twice the value at 30 MHz. If the impedance at 30 MHz does
not impair the efficiency of the amplifier to a significant
degree, how can this modest increase be effective in suppressing
the parasitic?

3. It has previously been suggested on this newsgroup that to
resolve stubborn parasitics, a capacitor can be placed in
parallel with the inductor, with the pair tuned to the undesired
frequency. Given my assumption that 811A's are unlikely to
oscillate above 70 MHz, should this perhaps be a routine
technique for these particular tubes?

4. Again, with a capacitor in parallel, should the resistor be
removed or increased in value, in order to improve the Q of the
suppressor? Wouldn't this improve its rejection of the
parasitic, while minimizing its effect on signals at the desired
frequencies?

5. Finally, regardless of whether the resistor is removed, what
type of series capacitor should be used (disc, sm etc.)? My
calculations of the suppressor as an independent network indicate
that resonating the coil at 60 MHz would require a 55 pf
capacitor.

Thanks for taking time to read this. Any and all input on this subject
will be appreciated.

73,

Jack WB3U

Most ordinary spray paints, such as the Krylon brand, work fine. Of course the best paints are labeled as radome paints and are properly characterized for RF use. Not cheap. The ordinary paints work nearly as well, as long as they aren't metalized. You want to avoid paints with "metalflake" because they will scatter the desired signal.

Strive for an even coat so that the dielectric constant over the face of the dish will be uniform. Painting reflectors has minimal effect on their electrical properties of interest. Painting linear elements, such as yagi elements, does have an effect on their electrical length due to the change in dielectric constant from air to that of the paint. This has a shortening effect on the elements, IE resonance will occur with slightly shorter painted elements than with bare elements since paint has a dielectric constant greater than 1.

Bingo! It's the frequency translation error that gets you. If you have
any frequency translation error, the harmonic relationships of the
speech (or music) components no longer line up. So instead of nice
harmonies, you have dissonance which is very grating to the ear.
It's like listening to a musical instrument that isn't tuned on a
well tempered scale.

Gary

From: ebarbour@netcom.com (Eric Barbour)
Subject: Wanted: someone to test RF power tubes

VACUUM TUBE VALLEY needs someone with experience in building
Class C tube amps. You would need to construct (or use, if you
already have one) a test box for RF power tube exercising.
This would just have a fixed plate supply and variable grid bias
to allow testing anything from 811s to 3-500zs to (perhaps) 833s.
Frequency anywhere from 10 MHz to 100 MHz, latter preferable..

You would be sent sample tubes to test and (usually) keep for
your own use. Just tabulate the peak RF output into a dummy
load of 75 ohms and note any problems (bias instability etc)
and possibly help with writing article text (most of this
would be my responsibility).

There may be some money in this, usually $100-200 for each
published article. Each article will focus on a single tube
type and have tests of various versions of it.

If interested (and serious), e-mail me.

Group delay is audible if it is bad enough. This is the *click-boom*
effect that plagues some loudspeaker designs, IE the path for the
high frequency components is a different length than the path for low
frequency components with the high frequency components typically
arriving first. This causes the "click" of a percussive drum strike
to arrive before the "boom" of the drum. Instead of kaboom, you hear
click <pause> boom. It's less noticable on speech, but it's there,
and adds to listener fatigue. However, the group delay through an
RF filter is so small compared to the time of an *audio* cycle
as to be insignificant. You can't hear it.

The much more serious effect for SSB is frequency mistranslation.
This causes harmonic dissonance, and the ear is very sensitive
to that. For example, a speech component that has a 16 Hz, 32 Hz,
and 64 Hz harmony, will be dissonant if the frequency translation
error is 10 Hz so that you now have the sequence 26 Hz, 42 Hz,
and 74 Hz. The tones are no longer harmonically related, and
sound dissonant to the ear. This is still noticable to the ear
at higher frequencies where the error is a smaller percentage.
You have to get the error down under a couple of Hertz for the
ear not to detect it. Otherwise, the harmonic "beat" will cause
a warble that's noticable to the ear. An example is a guitar that
is slightly out of tune, you can notice the beat even though it's
at a frequency below the audible range.

>I suspect the main culprit is the nonlinear distortion
>in the average SSB transmitter.

This is certainly a factor with amateur gear. The frequency
response of the entire chain, microphone, speech amp, compressor,
DSB generator, filter, and linear amplifiers, all have an effect
on speech quality. And similarly, all the stages of the receiver
also contribute. Aside from frequency mistranslation, the most
striking effects occur in the audio stages at both ends. For some
reason, amateur manufacturers seem to think 10% THD is a *desirable*
specification for the audio sections of their radios.

One of the best things you can do to improve the fidelity of your
radio is to improve and flatten the response of your audio stages. A
receiver audio stage that has flat response from 20 Hz to 20,000 Hz,
and that has 0.01% THD, will sound worlds better than one that is
constricted and distorted, and will lead to *much* less listener
fatigue. The same can be said for the transmitter audio stages.
In this regard, the use of audio filters on receivers should
strongly be discouraged. The group delay through such filters *is*
significant compared to an audio cycle, and *is* audible. Do your
selective filtering at RF where the group delay is an insignificant
portion of an audio cycle.

Gary

2224. Help with Homebrew Plate Choke

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-27 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3q89bv$2lg@misc1.microserve.net>
Source record: 112628

Yesterday evening I began experimenting with construction of homebrew RF plate chokes. The object was to determine the optimum number of turns and spacing, within the constraints of minimum required inductance, in order to eliminate series resonances within the ham bands. Measurements with a GDO have produced results that I can't explain - perhaps someone can help me with this.

To begin, the form used for all my experiments is 1" diameter styrene. The windings consist of a single layer of close-wound enameled magnet wire.

The first series of chokes I wound were made of #26 wire, initially wound with 115 turns (approximately 2-1/4" long). Measurements indicated internal series resonances at 26 MHz and 35 MHz. To move the lower resonance out of the 1.8 - 30 MHz range, I gradually removed turns from the coil. By the time I was down to 80 turns (about 1-1/2" long), the lower resonance had moved up to 33 MHz.

Here's where it gets odd. Not satisfied with a resonance that was still so close to the 10 M band, I decided to try splitting the coil into two sections rather than removing more turns. So, at a point about 3/4 of the way from one end, I added a 1/2" space. The coil still had the same number of turns and was still close wound, but was now 1/2" longer than before, due to this space. To my surprise, the lower series resonance point went *down* to about 30 MHz, rather than moving up as I had planned.

I later repeated this experiment using #22 wire on the same form. With 100 turns close wound, the lowest resonance was 29 MHz. Adding a 1/2" gap at approximately the midpoint caused this to shift down to about 27 Mhz.

Does anyone know why this is happening? Isn't the series resonance supposed to be the result of coil inductance and distributed capacitance? Shouldn't both of these factors be reduced by adding a gap between the windings, and shouldn't this cause the resonant frequency to increase?

Any opinions or explanations for this will be appreciated.

73 & Thanks,

Jack WB3U

Source record: 112629

Nonlinear distortion doesn't necessarily sound bad. Witness the Aphex box used by professional audio engineers to add distortion to certain musical tracks before the mix. Note also that some ham transmitters are reported to have subjectively better audio with the processor turned on. The gently saturating kind of distortion is similar to that produced in the ear itself and is perceived as loud, not distorted.

Phase distortion is not audible, but may change the character of subsequent nonlinear distortion. The result may be an unfamiliar sound which is perceived as rude or ugly.

Another important kind of distortion, which I did not see mentioned, is unintentional angle modulation. The worst example is an old modulated oscillator AM rig, which has FM as well as AM. Audiophiles know about this and prefer a separate tweeter to a whizzer cone mounted on a woofer. You don't want the tweeter moving back and forth with the bass sounds and changing the delay of the treble sounds. In a transmitter we don't want microphonics or poor supply regulation to chirp one of the oscillators or reactance-modulate a narrowband amplifier. What happens to SSB theory when the transmitter carrier is not frequency and phase stable?

Nitpicking aside, I disagree that SSB has to sound bad. Like many hams I sometimes use a receiver with good audio, so I can hear the difference between transmitters. Some are at least as clear as a digital telephone connection -- am I too easily pleased? If it matters, the receiver has a broad four-pole crystal lattice filter, no synthesizer, external DC power, and cheap LM380 class-B audio output.

Maybe I just don't see this as very much of a problem, since I use a continuously tuned receiver with a BFO. If the tuning isn't spot on, the frequency translation error is very audible and offensive, but even with it set perfectly, the audio quality is poor.

Now, I am assuming that there is some sort of error such that there is still not linear translation of frequencies across the band, and that with the BFO set for 1:1 translation of midrange frequencies, the high and low end may still be offset somewhat.

However, I don't have my copy of Terman handy here, or the ability to do the math without. But are we getting close here?

Those sort of things look attractive for tube amp PSU's, but I've been told they are
not designed for the ripple of a 50/60Hz supply, so fail quickly if used in that
service.

I dont know the specific cap being sold - its just a general warning.

Subject: High intercept, low noise amp - wanted.

I'm looking to build a lowish noise (2-4 dB) amp for about 70 or 100MHz
with a 3rd order output intercept of > +50dBm . Gain about 15dB.

Getting the nosie figure is easy. Getting the IP3 is easy, but getting the two
together is beyond me. Since I dont have access to NF measuring gear, I was
idealy looking for a circuit known to work. Failing that, any pointers on how
it might be done. I can measure IP3.

From: w8jitom@aol.com (W8JI Tom)
Subject: Bias circuits for solid state amplifiers

But remember that the bias current through the diode has to exceed the peak base current several times over or else the bias will wiggle around with drive. That will cause gain compression, splatter, and distortion (as many VHF/UHF operators living near people using diode biased amplifiers can attest to).

It is almost impossible to place enough standing current in a simple diode bias circuit for good linear SSB operation at power levels over a few watts. The best circuits use a temperature sensing device along with an active regulator.

If the transistor has a current gain of 10 at the operating frequency, and draws 20 amps of peak collector current, the bias diode would require at least 10 amps of standing current to remain relatively stable, since the peak base current would be 2 amps! The bias current tries to push the transistor into cutoff, so you sure don't want it to wiggle much.

This is all that was posted. Do you need information?
The GE Mastar II was a building block radio that lends itself to becoming a repeater.
You need to remove the antenna switching functions and add a noise squelch switch

and an audio processor to create a repeater. If you use a commercial (re
QST ads) to conversion is
simple. Just add a duplexer.

Let me know if you need more details

From the Ham Radio magazine index published Dec 1973, I found the
following:
Converting a vacuum tube receiver to solid state p. 26 Feb 69
Short circuit p. 76 Jul 69
Converting vacuum tube equipment to solid state p. 30 Aug 68
Fetrons, solid state replacemnents for tubes p. 4 Aug 72
Pentode replacement p. 70 Feb 70

I had a listing of similar stuff in QST a while back, but I don't
know where I put it. Maybe someone with access to a composite
QST index can dig it out for us. I would also like to have
the references.

A long time ago (back in the 70s) I did successfully convert a
receiver (SX-99) to all solid state. It worked like a champ
after I cured all the gremlins due to the feedback in the IF
stages. More recently I reworked an old BC band command receiver
to cover 1.5 to 2 MHz and replaced the tubes with 40673 MOSFETS
and MPF102 FETs. Works like a champ. Never did get the AGC and
product detector put into it though. Maybe someday when I have
time, but alas, no source for the 40673 - RCA quit making them.
Does anyone have a stockpile? I'm interested in about a dozen,

73,
Don W3FPR

>>I've heard there may be large voltage spikes on the 13.8 volt DC power in
>>an automobile due to alternator/regulator switching (or something like that).
>>Does anyone know if this is true?

I had an experience with Regency RFH252 (XL2000) mobile radios that after
they had
aged for several years became very succeptable to noise spikes on the DC line.

Recency said that some brands of alternators had a very high, 200-500 volt, very short
duration spike. It seems the mobile cpu reacted to this spike by putting the worst
case of alternator whine. The radios would shift frequency, over-deviate, under-deviate
you name it. Turn of the engine, perfection.

Maintenance free batteries are a curse in this situation. Most of these batteries
have a higher characteristic impediance to this kind of noise. Good ol' lead acid works
just fine.

Another factor I have found in 30 years in Avionics/Land Mobile is bad grounds.
Auto engines are poorly bonded to the vehicle chassis and therfore most DC grounds.
Measure between the alternator frame and chassis with a heavy load (heaters, highbeams etc.)
and observe the voltage. Improve the bonding on these grounds and a lot of your noise will vanish.
Too mush time is spent conditioning the + side of the line without considering the negative side.

I have embarased more that a fair number of competetiors by ripping out their "noise filters'
and cleaning an installation with bonding straps

>Don't think that's the way it works. At any one location the reading stays
>pretty constant, and if the error were really like noise it would seem like
>you could just average a lot of readings to get a more accurate fix.

In fact you *can* do just that. The SA dither is symmetrical, and if
you time average long enough, you'll come to a position fix that's at
least as good as the differential method. With a single reading in SA
mode, your accuracy is only +/- 100 meters, and if you watch closely,
succeding position plots will wander about inside that circle in a
good approximation of random order. If you average enough points, you'll
get a position fix down to under the +/- 10 meters promised by differential
GPS. (For most receivers, this variation is most easily watched by looking
at the altitude reading, which usually reads out directly in meters
above MSL.)

From a military point of view, that's fine, because all they're concerned
about is someone using a civilian GPS to guide a el cheapo cruise missile.
By the time you time average enough readings in that case, the missile
is somewhere else, so that technique doesn't pose a threat. Time averaging
is useful, however, for geodesy since you can leave the receiver at the
point you are surveying long enough to get a meaningful time average of
the readings.

Note that the receivers themselves use time averaging. While they only
update their display once a second, that update is the result of averaging
many readings internally during that second. That short an averaging
period, however, won't do better than +/- 100 meters. If you average
over several minutes to hours, however, then you start to tighten your
fix significantly.

Gary

>broadcast from things such as a weather station or such,this is his email.

It's still a point to point transmission in a closed network of stations,
the definition of auxillary operation, and one way transmissions are
specifically authorized for auxillary operation.

>A little different. Also he could transmit over someone else and that is
>not allowed.

Unfortunately, it is not forbidden, but that's basically irrelvant
for auxillary operations. They take place on *link* frequencies that
are usually coordinated. Like any other link, such as to a voter from
a remote repeater receiver, there is no obligation in practice to check
if the frequency is in use before transmitting because the frequency
is coordinated for the auxillary station's use. Ordinary "bulletin"
stations, such as W1AW, don't listen before transmitting either, nor
do beacons, nor do telemetry links from balloons, model craft, etc.
These types of one way transmissions are specifically authorized in
the rules, and there is no requirement to even have a receiver at
the transmission point that can monitor the transmitting frequency.

From: jhschutt@figmnt.tayloru.edu
Subject: Please help my son!!

My son is a ham and is interested in building electronic circuitry. He wants
to build a QRP rig for 40M. Can you help with the following:

1. What's your favorite source for parts? He has JDR Microdevices' catalog
and Radio Shack's catalog.

2. Do you have a favorite circuit? He's been looking in the ARRL handbook and
in QRP.

Thanks in advance!! Pls e-mail to the address below.--

From: davek@medphys.ucl.ac.uk (Dave Kirkby)
Subject: SSB - why poor sound quality?

Like many hams, I predominately send (when I had a TX) and receive SSB. However,
to my mind, the sound quality is not as good as an AM transmission, using a 6KHz
bandwidth for AM. Why?

I realsise the SSB bandwidth is less than half the AM one, but both contain only the 300-3000Hz frequencies. Sure AM takes up more space, but an AM TX just sends two copies of the sidebands. So SSB's more efficient use of bandwidth should not mean a redection in quality.

Perhaps other people disagree, but I'm convinced SSB does not sound as good as an amateur AM signal. Obviuosly one would not expect it to sound like a commercal AM signal, where the bandwidth exceeds the 300-3000Hz.

My thoughts as to a possible explanation are:

1) Would a typical AM signal send from very low frequencies (say 20Hz) to 3KHz, since there is no point restricting the lower ends? Since although the signal takes up less bandwidth, its most unlikely anyone else can use the space between the carrier and the lower limits of the sidebands. Perhaps then the 20Hz to 300Hz information makes the signal sound better.

2) Its very difficult to re-insert the carrier at precisely the correct frequency at the receiver. I've recently used a 2m transceiver as a tuneable IF for an HF receiver I'm biliding, The fact the tranceiver only steps in 100Hz steps definately causes poor quaility audio, but I've noticed this with VFO's too.

3) Perhaps there need to re-inser the carrier at the correct amplitude, or in the correct phase. I've never looked at the maths to say if this is true.

Any thoughts?

dave kirkby G8WRB.

I can't agree with you on this Gary. Telemetry implies information being broadcast from things such as a weather station or such,this is his email. A little different. Also he could transmit over someone else and that is

not allowed. I think it is a good idea for his pager but I just don't
think it is totally legal. If he checked that the frequency was clear,
then used his 220 meter radio to tell his computer to send the email, that
would work.

2231. Wanted: someone to test RF power tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-27 00:00:00 UTC
From: ebarbour@netcom.com
Message-ID: <ebarbourD986C8.E5v@netcom.com>
Source record: 112635

VACUUM TUBE VALLEY needs someone with experience in building
Class C tube amps. You would need to construct (or use, if you
already have one) a test box for RF power tube exercising.
This would just have a fixed plate supply and variable grid bias
to allow testing anything from 811s to 3-500zs to (perhaps) 833s.
Frequency anywhere from 10 MHz to 100 MHz, latter preferable..

You would be sent sample tubes to test and (usually) keep for
your own use. Just tabulate the peak RF output into a dummy
load of 75 ohms and note any problems (bias instability etc)
and possibly help with writing article text (most of this
would be my responsibility).

There may be some money in this, usually $100-200 for each
published article. Each article will focus on a single tube
type and have tests of various versions of it.

If interested (and serious), e-mail me.

Thanks for the info and the kind words. Believe me, these calculations are purely for my own survival. I've learned from experience that there's a fine line between cut and try, and cut and give up.

There are a few of your answers that I don't fully understand and I'd like to go over the fine points one more time. Bear with me on this - I spent a lot of time on this amplifier during the last go 'round. I want to start the next session with my eyes open.

>Keeping the grid inductance as low as possible moves the parasitic up

>chip of at least .01 mFd with "zero" lead length. It is critical that
>the caps series resonant freq be close to or above the tube's self
>neutralizing freq.

The original capacitors are .0047 disc ceramics with *very* short leads. To these I added 100 pf discs with even shorter leads. When you say "multi-layer chip", are you describing leadless capacitors? If so, I would worry that the stress of inserting and removing the tubes would eventually break the capacitors. These aren't the type of sockets that have pin holders riveted to the ceramic - the pins in these are free to move side-to-side like sockets for receiving tubes. Regarding the resonant frequency of the caps, doesn't the 60-70 MHz limit of the tubes allow the luxury of *moderately* greater lead lengths than would be the case for tubes like 3-500Z's?

>The ideal suppressor coil would have a very high Z at the frequency
>of the parasitic, and no appreciable R or Z at the operating
>frequency to prevent a loss of harmonic suppression and tank Q.

To me, this sounds like a suppressor that would consist of a parallel-resonant L/C network with no resistor. You later state, however, that the resistor cannot be removed. This means that perhaps I don't understand what's happening at the plate, relative to the parasitic. To help clear this up, I will describe my logic regarding this circuit as follows:

In order to reduce gain at the frequency of the parasitic, two things should be done. First, the internal feedback path must be neutralized,

and second, the external feedback path (plate to cathode or output to input) must be broken or at least impeded. The external path can be disrupted by either shunting the undesired frequency to ground, or by selectively routing undesired frequencies to a higher-impedance path.

The typical L/R parasitic suppressor attempts to do the latter, but because many types of amplifier tubes can oscillate over a fairly wide range of frequencies, the network must have a relatively low Q. This is moderately effective at suppressing the undesired frequency band, but because of the compromise between bandwidth and Q, the suppressor cannot provide significant loss to the undesired frequencies without also introducing loss to signals within the desired range.

The situation with 811A's is somewhat different, insofar as the undesired frequency band is relatively narrow due to the upper frequency limit of the tubes. Therefore, increasing the Q of the suppressor may be an effective means of reducing loss on desired frequencies, as well as providing additional attenuation of undesired oscillations.

Rather than constructing a L/R network that exhibits 23 ohms at 30 MHz and 50 ohms at 60 MHz (see previous calculations), why not increase the value of the resistor significantly (or eliminate it altogether), decrease the inductance of the suppressor coil, and add a capacitor across the coil sufficient to achieve a high Q L/C suppressor?

By way of example, say that we eliminate the resistor from the suppressor, then reduce the coil from 6 turns to 3 turns (0.032 uH). This will reduce the XL at 30 MHz from 24 ohms to only 6 ohms. If a 220 pf capacitor is now paralleled with the coil, the network will resonate at 60 MHz. Assuming a (conservative) Q of 10, the parallel resonant impedance at 60 MHz will increase from 49 ohms to approximately 120 ohms.

To go a step further, the half-power bandwidth of the suppressor would be approximately 6 Mhz, with significant suppression of undesired frequencies extending a considerable distance beyond that range. If the bandwidth *had* to be increased, a parallel resistor could be added, bearing in mind that it will reduce the impedance to undesired frequencies.

In summary, the above example reduces the impedance seen on the desired frequency from approximately 23 ohms to 6 ohms. It further increases the impedance presented to the parasitic from 49 ohms to approximately 120 ohms. The latter number could be much higher, depending on network Q, or lower if wider bandwidth is required.

BTW, now that I've done these calculations, I understand the fallacy of the nichrome. Considering how little impedance difference there is in an L/R suppressor between desired and undesired frequencies, the last thing the circuit needs is a further lowering of Q.

So, comments on the above? Is this workable, or am I misinterpreting the workings of the parasitic tank? Given the numbers I came up with previously, I'd sure like to get rid of those resistors!

>Subject: Component Values for Parasitic Suppressors?

>The original capacitors are .0047 disc ceramics with *very* short
>leads. To these I added 100 pf discs with even shorter leads.

100 pF may only be a change at high VHF, and not at HF or low VHF.
With the 100 pF you may have been better with long leads, so the cap
was series tuned at the parasitic frequency!

>When you say "multi-layer chip", are you describing leadless
>capacitors?

You can get them with leads. The main point is to avoid adding an
unwanted parallel resonance from the grid to the chassis. That would
aggravate instability (like the grid chokes in parallel with the grid
bypass caps in the TL-922 and SB-220 do).

>If so, I would worry that the stress of inserting and removing the
>tubes would eventually break the capacitors. These aren't the type of
>sockets that have pin holders riveted to the ceramic - the pins in
>these are free to move side-to-side like sockets for receiving tubes.

That is a problem, but you could add a flexible lead as short and as
wide as practical to eliminate the breaking problem.

>Regarding the resonant frequency of the caps, doesn't the 60-70 MHz
>limit of the tubes allow the luxury of *moderately* greater lead
>lengths than would be the case for tubes like 3-500Z's?

Ahh, that's a very good point you brought out. You've got a good
understanding of the problem!

What you say is true. But I was giving the easiest explanation and the
best "general rule". So while you probably can be a good bit less
careful with the 811's external grid lead lengths because they are so
LONG in the tube already, I wouldn't make that a habit for other tubes.
Better to make it a safe general statement that won't get someone else
in trouble.

>The ideal suppressor coil would have a very high Z at the frequency
>of the parasitic, and no appreciable R or Z at the operating
>frequency to prevent a loss of harmonic suppression and tank Q.

Read it this way...The ideal suppressor COIL (not the whole
suppressor, just the COIL) would have a very high Z at the frequency
of the parasitic. The COIL would have no appreciable INTERNAL
R (and minimal Z) at the operating frequency to prevent a loss of
harmonic suppression and tank Q. In other words the coil would look

infinitely large at the parasitic frequency, and like an absolute short at
the operating frequency. I'm not talking about the entire suppressor,
just the coil of the normal suppressor. A resistor must still be in
parallel with this coil, or there will be no VHF dampening.

>In order to reduce gain at the frequency of the parasitic, two things
>should be done. First, the internal feedback path must be neutralized,
>and second, the external feedback path (plate to cathode or output to
>input) must be broken or at least impeded. The external path can be
>disrupted by either shunting the undesired frequency to ground, or by
>selectively routing undesired frequencies to a higher-impedance path.

No, the undesired frequency must be dampened with degeneration or
dissipative loading that reduces the gain at the oscillation frequency.
The remaining (suppressor loaded) gain must be less than the amount
of regenerative feedback.

>The typical L/R parasitic suppressor attempts to do the latter, but
>because many types of amplifier tubes can oscillate over a fairly wide
>range of frequencies, the network must have a relatively low Q.

That's correct. But the circuit parameters affecting this Q are too
complicated to explain without drawings.

What it boils down to is keeping the anode lead short and wide
between the tube and the tuning capacitor, mounting and grounding the
tuning capacitor as near the tube as possible and to the same sheet
metal to ground all the RF grounds (including the grids). That lets you
use the lowest value of R, and values between 30 and 150 ohms almost
always work fine for the tubes amateur power levels require. Finally
the resistor must be the dominate thing in the anode to tank path at the
frequency where instability occurs. That requires a low reactance in
series with the R, and a high parallel reactance shunting the R.

>is moderately effective at suppressing the undesired frequency band,
>but because of the compromise between bandwidth and Q, the
>suppressor cannot provide significant loss to the undesired
>frequencies without also introducing loss to signals within the desired
>range.

That's why I suggest using tuned suppressors if the tube oscillates near
the operating frequency, shunt L / series C suppressors if the tube
oscillates at moderate distances from the operating frequency, and a
conventional suppressor if the tube oscillates a good distance above the
operating frequency.

Try your calculations again for a suppressor like this...Put a coil in
series
with the anode lead. Connect a capacitor in series with the suppressor
resistor and connect that across the coil. Now the current shift to the
resistor happens twice as fast, so the loading goes up at the square of
the frequency ratio, instead of at a linear rate. In other words, with the

coil in parallel with the R, the current shift from the coil to the R is linear, doubling the freq. will only double the circuit loading by R.

If I have a series RC circuit paralleling the suppressor's coil, the capacitive reactance can be used to decrease the impedance of the path through R as the normal suppressor coil's reactance increases with frequency. The loading increases twice as fast as with the basic suppressor, and fundamental current through the lossy R is reduced!

You can model or calculate the effects of a series RLC circuit resonant near the parasitic frequency placed in parallel with the regular suppressor coil. In severe cases you could even parallel tune the conventional coil while series tuning the dissipating RLC path at the parasitic frequency.

>The situation with 811A's is somewhat different, insofar as the
>undesired frequency band is relatively narrow due to the upper
>frequency limit of the tubes. Therefore, increasing the Q of the
>suppressor may be an effective means of reducing loss on desired
>frequencies, as well as providing additional attenuation of undesired
>oscillations.

Actually the "undesired frequency band" is usually pretty narrow with all tubes. There is usually a narrow range of frequencies where instability occurs. Remember the grid resonance *usually* dominates the frequency of the oscillation, and the anode resonance must *usually* match the grid for a problem to occur. So if we just dampen the anode at the frequency where the grid "floats", we will usually be OK. Some tubes (like 8877's) won't ever oscillate if the grid is grounded correctly no matter what is done in the anode.

>Rather than constructing a L/R network that exhibits 23 ohms at 30
>MHz and 50 ohms at 60 MHz (see previous calculations), why not
>increase the value of the resistor significantly (or eliminate it
>altogether), decrease the inductance of the suppressor coil, and add a
>capacitor across the coil sufficient to achieve a high Q L/C
>suppressor?

Because that won't suppress at all. There would be little or NO dampening loss! That would actually make it worse, because now the anode would be free to "wiggle all around and tickle the grid". You've just made an unloaded TPTG oscillator!

>By way of example, say that we eliminate the resistor from the
>suppressor, then reduce the coil from 6 turns to 3 turns (0.032 uH).

>resonate at 60 MHz. Assuming a (conservative) Q of 10, the parallel
>resonant impedance at 60 MHz will increase from 49 ohms to
>approximately 120 ohms.

I doubt if the LC network Q would be that low. But it certainly would if the LC network were loaded with a 100 ohm resistor! Anyway, even 100 ohms of series XL on 30 MHz has a negligible affect on the 10

meter performance. The problem is really keeping the lossy R out of
the circuit on 30 MHz, and keeping it in the circuit at 60 MHz or so.

>To go a step further, the half-power bandwidth of the suppressor
>would be approximately 6 Mhz, with significant suppression of
>undesired frequencies extending a considerable distance beyond that
>range. If the bandwidth *had* to be increased, a parallel resistor
>could be added, bearing in mind that it will reduce the impedance to
>undesired frequencies.

We don't want impedance, we want resistance at the undesired
frequencies. We want a "pure impedance" at the desired frequencies,
since that is non-dissipative. We just can't have that impedance so large
it upsets the tank operation or tube to tank coupling excessively.

>BTW, now that I've done these calculations, I understand the fallacy
>of the nichrome. Considering how little impedance difference there
>is in an L/R suppressor between desired and undesired frequencies,

Yes, and the nichrome is in the path that mostly affects the HF signal,
not the parasitic!!!!! What a bunch of hooey!

There are a large number of Japanese N-Channel dual-gates that should substitute very well for this device. Audio service companies use these, mostly as replacements in FM receiver front ends.

I believe one of the common numbers we used was a 3SK140, but I've been out of the industry for a number of years. You should be able to verify a few suitable numbers with a local audio/video technician.

Hello Jeff,

The homebrew choke is resting on a stack of papers on my desk.
Every time I remove turns, I cut off the excess wire and short the
choke with its own leads.

To roughly locate the resonances, I couple the GDO tightly to the
choke, sometimes placing it inside the form. After each point is
located, I move the GDO coil away from the choke until the dip is
barely perceptible, then re-dip. The coil of the GDO is parallel to the
choke at all times.

Frequency of the readout was verified by tuning the GDO across the
nearest ham band (in this case, 10M) and listening for the oscillator.
I left my receiver tuned to 28.0 MHz during these tests and I checked
the dial accuracy frequently.

Any ideas?

This is also known as Doppler distortion, and I strongly question whether whizzer cones suffer because of this, or rather because this type of tweeter simply can't reproduce high frequencies. Despite assertions by the "experts", I've never been convinced that this type of distortion is discernible as "bad". Some of the early planar speakers had a superb sound quality and only used a single diaphragm to cover a very wide range of frequencies. Also, microphones don't have separate elements for different frequencies - the highs are constantly modulated by the lows. As far as I'm concerned, the only reason to break up the reproducers into different units is to better match the frequency response and power handling capability of each type speaker.

Jack,

I think the error was removing turns without any idea where the resonances are formed in the choke. The distributed capacitance from one area of the choke to another, combined with the inductance leading to that point, form these series resonances.

In order to increase the series resonant frequency, turns must be removed from the area that has the largest effect on the unwanted resonance. Removing turns from any other area can cause unexpected changes.

I prefer using my network analyzer to test chokes, but I can still do the nearly same thing with two methods. The first uses a light bulb, a tee connector, and a continious frequency range transmitter, the second uses a MFJ-259 SWR analyzer (or similar).

To do the first test, I connect the radio to a dummy load through a tee connector. I mount the choke in the operating position and connect the bottom of the choke to the amplifier circuitry in the expected fashion. I do NOT connect the top of the choke to anything. I set the bandswitch to 160 or 80 meters and fully mesh the capacitors to prevent tank circuit suck-out errors.

With everything in the amplifier as close to the normal physical operating position as possible, I position the tee connector against the chassis of the amplifier. I insert a 50 to 100 mA low voltage lamp with a short leads going to the choke and a longer lead going to the center pin of the tee connector.

Apply enough RF to barely illuminate the bulb and sweep upwards in frequency until the bulb starts to glow brightly, reducing the RF level so the bulb doesn't fail as it glows brighter.

When you find a point of maximum illumination, it is a series resonant point. If you move the blade of a screwdriver along the choke you will find a point where the quickly lamp dims. That is the "hot spot" for that choke *as mounted in the actual operating position*. If you remove turns from ONLY that general area, that particular series resonance will move up in frequency rapidly. The other series resonances will move in smaller unpreditable amounts. This allows you to create a rough twisted and soldered prototype choke that you can *copy* with a single neat winding.

The same steps can be done with a MFJ-259 by connecting it between the chassis and the choke top. Follow the instrutions above by watching the SWR or impedance (called RESISTANCE) meter on the

259. The lowest SWR and impedance is the series resonant point. In this case move the screwdriver along the choke until the resonant point is indicated by a sudden increase in the SWR and impedance.

I hope this helps and was clear enough.

2244. QRP discussion group

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-28 00:00:00 UTC
From: Mike.Czuhajewski@hambbs.wb3ffv.ampr.org
Message-ID: <1995May28.143404.29368@wb3ffv.ampr.org>
Source record: 112648

For the benefit of those interested in QRP who did not see the posting by Chuck Adams (K5FO) over on rec.radio.amateur.misc, there is a new home for the QRP discussion group (mailing list). It is now at lehigh.edu. If interested in signing up, send e-mail to

listserv@lehigh.edu

and in the text say

subscribe QRP-L name callsign

For example, subscribe QRP-L Mike Czuhajewski WA8MCQ. The reason for the additional info is that the system is running ListProc instead of majordomo, and when you query it for a list of everyone on the list it will give you their names and calls in addition to e-mail addresses.

IMPORTANT NEWS: The daily digest function is available, and operational, on this host. While the software at netcom.com had the digest function available, it was not implemented. If you want to get an entire days postings bundled into a single e-mail message, use the digest function. When you subscribe, you will get a welcoming message and it will contain full info on the digest and other features.

John,
My favorite is the rig that Dave Benson (NN1G) designed. The NE40-40 is the rig that covers 40 Meters. Dave sells kits as Small Wonder Labs, 80 East Robbins Ave., Newington, CT 06111. The kit contains the circuit board, all onboard components. You need to provide connectors, case and a couple of pots. I was delighted with the quality of the kit that I built.

I believe that Dave does have an email address now, however I don't have it handy.

>was series tuned at the parasitic frequency!

Tom, this oscillation never seemed to be affected by anything I did at the grids, as though the original caps were indeed effective at bypassing all RF. This fact notwithstanding, won't the length of the grid lead inside the tube become part of the series XL of the bypass capacitor? Is there a way to estimate the inductance of the internal grid lead, so that an external cap can be more accurately tuned?

>Try your calculations again for a suppressor like this... <snip>

I'm going to attempt this with my spreadsheet, but first, I want to be sure I understand what you're saying regarding the function of the resistor in the suppressor. As you mentioned, it's difficult to go into detail without a drawing. Still, maybe if I make a few summary statements based partly on the remainder of your reply, you can tell me if I'm on the right track.

1. Neutralization may not be sufficient to suppress VHF parasitics due to the lead lengths of the neutralizing circuit. Its primary effectiveness is at lower frequencies.

2. The VHF parasitic can occur through two different feedback paths, internal and external to the tube, as I mentioned before. However, due to No. 1 above, the internal path cannot be summarily dismissed simply because neutralization has been applied. In effect, I missed this particular VHF feedback path in my previous hypothesis.

3. The external feedback path could be disrupted at VHF by using a parallel L/C suppressor with no resistor. This would present a very high impedance to the parasitic and would prevent this energy from flowing out to the remainder of the tank circuit.

4. Despite the statement in No.3 above, the internal VHF feedback path must have the resistor attached to the anode. A high impedance plate load at that frequency would allow the plate to be modulated by the natural VHF frequency of the internal G-P feedback path.

5. In order for the suppressor resistor to "load" the anode at VHF, the end opposite the anode must be attached to a point through which VHF currents can flow. This current path could be the stray capacitance to ground from the tank circuit and associated wiring, but it does not seem well-defined. This lack of definition for the VHF current path may be the reason why standard suppressor values

sometimes fail to work.

6. The ideal suppressor would pass the desired frequencies from the anode to the tank circuit with no loss, and would shunt the undesired frequencies to ground with no loss. The first requirement could be met with a parallel L/C suppressor between each anode and the tank circuit. However, the second requirement would mean a series L/C (or R/C) circuit from each anode to ground, not too practical.

Yes? No? Comments?

<snip>

This sounds entirely plausible to me. Unfortunately, I don't have either
a general-coverage generator, or anything similar to the MFJ analyzer.
I think I'm going to have to let this one go and rely on being able to
build a continuous-winding choke. This brings up another question . . .

At one point, I had the 1" diameter choke wound with 80 turns of #26, for a
total winding length of about 1-1/2". The only resonance near the ham bands
was at 33 MHz. With a calculated inductance of 82 uH and resistance of
0.82 ohms, the Q of the choke at 30 MHz calculates to more than 18,000.
Given this number, do I need to worry about the 33 MHz resonance? Will
in-circuit operation broaden the response, or is 33 MHz far enough removed?

Jack,

You might try dipping the choke with it in place, and the top shorted to the bottom. You could watch for the dip to move as you probe the coil. I have never done that, but it sounds like it may work OK.

>At one point, I had the 1" diameter choke wound with 80 turns of #26,

>resistance of 0.82 ohms, the Q of the choke at 30 MHz calculates to
>more than 18,000.

But that is a dc loss resistance and an very inaccurate RF impedance. The actual Q will be much lower. You obviously aren't planning on 160 operation either. It would be blind luck if the Q was even in the hundreds

at 30 MHz. That's a guess, but it is from measuring hundreds of chokes over the years on a Boonton Q meter and an HP network analyzer. And be sure you test with the choke mounted in place. Even the screws that hold the choke in place move stuff around a lot, so don't extend them up in the choke very far. BTW, the Q will go up a lot if you space wind the choke (around one wire diameter).

You really should measure the impedance of the choke at 30 MHz. I understand the lack of enthusiasm to build a test fixture to measure one choke, since that is a construction project by itself. That is why people just cut and try. If it works they don't worry about it. Are you sure you can't easily modify your radio to transmit outside the band?

>Given this number, do I need to worry about the 33 MHz resonance?
>Will in-circuit operation broaden the response, or is 33 MHz far enough
>removed?

I would be concerned only if the choke shifted down in frequency when installed near other objects. It is really an impedance ratio and voltage problem, if the tubes operate at a high operating plate load resistance (E/I
of the RF fundamental voltage at the anode) it could become a matching complication if the choke impedance goes far below the operating plate resistance value. If the voltage across the choke is high and the impedance and Q are low, the choke may also dissipate excessive power and overheat. If the choke is at or very close to series resonance, extreme
voltages can appear across the choke and cause the choke to arc over to other objects. I've had chokes produce six or seven inch streamers with 7 kV power supplies (near series resonance)! How close? Usually within

five percent or so of the series resonant frequency. How will you know? Do the best you can and try it. Just be sure the supply is fused, that you

have a proper surge rated 20 to 50 ohm resistor in series with the HV lead, and you've gone to the bathroom, cause it's gonna make a bang if you apply power and the choke arcs to a grounded object!

>capacitor?

Yes. But bypasses series tuned with the grid XL will be too small at
the fundamental. It is all ready close since .0047 is 19 ohms
Xc at 1.8 MHz. That is marginal for the grid impedance of a
few hundred ohms per tube on 160. I've used that effect to effectively
bypass VHF amplifier grid leads.

>Is there a way to estimate the inductance of the internal
>grid lead, so that an external cap can be more accurately tuned?

Yes, but the details are complicated. In short, the anode to cathode
feedthrough is measured at VHF, and the grid capacitor is adjusted for
a null in the feed through power. After that is done you could add a
seperate low frequency bypass that has a high VHF impedance. The
problem is this method can create holes in the bypassing at the cross
over frequency that may destabilize the amplifier at those frequencies. I
think that method should only be used in very specific design
applications. I used it once in a third harmonic resonated class C
amplifier to acheive ~96% plate efficiency, but that was a single
frequency fixed tuned PA and it was from the screen grid to ground.

>flowing out to the remainder of the tank circuit.

No, the problem isn't the series resonance to the rest of the world in a good layout. The problem is a high parallel impedance at the anode of the tube allowing the plate of the tube to move around easily. The high plate load impedance increases the voltage gain at the parasitic frequency. The voltage gain is always a strong function of the anode load impedance, and goes up with a higher anode load impedance. An unloaded suppressor could aggravate this condition.

>4. Despite the statement in No.3 above, the internal VHF feedback

Yes, the anode path to ground must be a short, wide good VHF path!
The suppressor resistor should dominate that path.

>6. The ideal suppressor would pass the desired frequencies from the

(or
>R/C) circuit from each anode to ground, not too practical.

No, it always needs that load resistor in the ground path for VHF. We want to shunt those unwanted frequencies to ground with loss so the Q is low, but a low enough resistance loss so the gain stays low. Even if it
is a separate series tuned VHF path from anode to ground.

Some of us have been lucky enough to play with receivers using IF DSP's. When you have available highly adjustable digital IF Bandpass filters, digital demodulation, and one Hertz tuning steps, SSB sounds like a guy talking across the table (given a decent multi-thousand dollar transmitter.) In just 5 or 10 years, when IF DSP technology is affordable on any decent receiver, we will look back on this discussion and laugh about the good ole days...

>signal sound better.
>
If you include the full audio bandwidth SSB will sound more "natural". It will
not perform as well under noisey conditions, though. As it turns out the
majority of the "intelligibility" of speech is in the higher frequencies of the
speech spectrum, above 1kHz. So if you accentuate them slightly you may get a
harsher sounding result; but, that result will cut through noise much better
than one with most of the power wasted in bass notes. Most users of SSB intend
to get their signals through rather than sound natural. "Natural sound" is an
"FM thing." (Which should bring a few people down on me I bet. {^_-})

Another thing that will degrade the "fidelity" of SSB speech is the MUCh higher
level of speech processing that is usually applied to the signals. ALC is only
part of the game. Another part performed by some radios involves clipping the
generated SSM speech and then refiltering to remove the clipping generated
frequencies outside the signal passband. This can also significantly increase
the percentage of the PEP used for the speech. Again, sounding better is not the
usual design goal. The usual design goal is intelligibility rather than
"fidelity".

A third factor is the number of hams who overdrive their rigs way beyond what is
necessary. A pegged ALC meter is NOT a sign of good operating practice. {^_-}

>2) Its very difficult to re-insert the carrier at precisely the correct frequency at
>the receiver. I've recently used a 2m transceiver as a tuneable IF for an HF receiver
>I'm biliding, The fact the tranceiver only steps in 100Hz steps definately causes
>poor quaility audio, but I've noticed this with VFO's too.
>

Over time you generate an ear for it. I have noodled out a design that would work to make the speech harmonics actually appear as harmonics of each other. But I figured this is more circuitry than is really needed, especially with modern synthesized radios. (If they are calibrated well and have good TCXOs driving them being 10Hz off is kinda "bad" at 14MHz or even 28MHz. And at 10Hz off things do not sound particularly bad. Even at 100Hz off intelligibility does not suffer much.) Reinjected carriers, even 20dB down, is a workable idea. It has never caught on because there are enough hetrodynes, sideband splatters, and other junk floating around on 20 meters, for example, without having your neighboring hams tossing in their own for good (bad?) measure.

>
>3) Perhaps there need to re-inser the carrier at the correct amplitude, or
>in the correct phase. I've never looked at the maths to say if this is true.

Depends on how "hi-fi" you want things. Again, the goal is intelligibilty not fidelity. I've performed enough tests myself and with others to know that these two concepts are at best "loosely" related and at worst inversely related.

Phase of the LO is not nearly the problem you'd like to make of it. I have, under strong signal conditions with neighbors, had them crank off on their audio gain, turn off speech processors, and run a more "linear" opreation. Then I have tuned carefully. When within a few Hz of their suppressed carrier things sound pretty decent. Once I toss in a little audio shaping I can make it sound pretty much like being face to face with them. This does not "get out" worth chicken droppings. Once he cranked it back up to normal things sounded much more "ham" than "broadcast." And once he turned on the processor things really went to <brown steaming stuff>. But THAT signal performed very well on 20. It cut through the interference and noise VERY well.

If you play with the trigonometry involved you'll find that DSB is a *VASTLY*
different kettle of fish than SSB. With DSB a modest phase error can translate
to a significant amplitude error on demodulation. With SSB this is most
defintely not the case.

Again, the BIG difference in fidelity between point to point SSB stations, which
are basically feeds for remote "commercial" broadcasts as often as not, and that
used by the military and hams comes from the demands of the respective services.
Point to point is demanding fidelity. So they work to achieve and maintain
fidelity. They get quite poor peak to average power ratios. So their signal's
"punch" must come from BIG amplifiers and antenna systems - and a nice clear
channel. For the ham and military and other COMMUNICATIONS use (as opposed to
"broadcast" use) the operative requirement is intellgibility. Without the big I
all the fidelity in the world does you no good at all. Processing the signal to
accentuate frequencies above 1KHz a few dB can make a wonderful difference in
how you get through at the expense of making you sound slightly "odd". (Er some
call it ridiculous.)

(W6SPK is a close friend of mine in the So Cal area. He has a nice deep voice.
He has had several different radios and mikes for use on the 440MHz repeater we

often use. The closer to "arog" he sounds the worse he "punches through" the average road noise in my VW bug convertible. When he uses one of the combinations that clips off most of the bass I have no problems at all understanding what he says. But he surely does not sound "normal." And he rather DISLIKES that. {^_-})

I have a 300 hz, 455 KHz Collins crystal filter, but no info on the thing.
Can anybody tell me :
- The source and load terminating impedances ?
- The 6:60 dB shape factor ?
- The insertion loss ?
- Pass band ripple ?

The type number is X455KF300

From: john.seboldt@blackboard.com (John Seboldt)
Subject: Bias circuits for solid state amplifiers

From: rohrwerk@netcom.com (John Seboldt)
You mention the bias diode method, and an active regulator method. I think it would be better to use the active regulator, because less idle current is drawn. The basic diode method is fine, but you have lots of current flowing through the series resistor and diode that is not destined for your transistor bases. It of course has the advantage of super simplicity. But I think you'll be happier with an active regulator with an adjustment pot so you can set bias to your liking; you'll get less wasted DC current to boot. I'll be building up the 140 watt amp kit from CCI, which uses the Motorola AN762 design.

Subject: Component Values for Parasitic Suppressors?

>Subject: Component Values for Parasitic Suppressors?

>The original capacitors are .0047 disc ceramics with *very* short
>leads. To these I added 100 pf discs with even shorter leads.

100 pF may only be a change at high VHF, and not at HF or low VHF.
With the 100 pF you may have been better with long leads, so the cap
was series tuned at the parasitic frequency!

>When you say "multi-layer chip", are you describing leadless
>capacitors?

You can get them with leads. The main point is to avoid adding an
unwanted parallel resonance from the grid to the chassis. That would
aggravate instability (like the grid chokes in parallel with the grid
bypass caps in the TL-922 and SB-220 do).

>If so, I would worry that the stress of inserting and removing the
>tubes would eventually break the capacitors. These aren't the type of
>sockets that have pin holders riveted to the ceramic - the pins in
>these are free to move side-to-side like sockets for receiving tubes.

That is a problem, but you could add a flexible lead as short and as
wide as practical to eliminate the breaking problem.

>Regarding the resonant frequency of the caps, doesn't the 60-70 MHz
>limit of the tubes allow the luxury of *moderately* greater lead
>lengths than would be the case for tubes like 3-500Z's?

Ahh, that's a very good point you brought out. You've got a good
understanding of the problem!

What you say is true. But I was giving the easiest explanation and the
best "general rule". So while you probably can be a good bit less
careful with the 811's external grid lead lengths because they are so
LONG in the tube already, I wouldn't make that a habit for other tubes.
Better to make it a safe general statement that won't get someone else
in trouble.

>The ideal suppressor coil would have a very high Z at the frequency
>of the parasitic, and no appreciable R or Z at the operating
>frequency to prevent a loss of harmonic suppression and tank Q.

Read it this way...The ideal suppressor COIL (not the whole
suppressor, just the COIL) would have a very high Z at the frequency
of the parasitic. The COIL would have no appreciable INTERNAL
R (and minimal Z) at the operating frequency to prevent a loss of
harmonic suppression and tank Q. In other words the coil would look
infinitely large at the parasitic frequency, and like an absolute short
at
the operating frequency. I'm not talking about the entire suppressor,
just the coil of the normal suppressor. A resistor must still be in
parallel with this coil, or there will be no VHF dampening.

>In order to reduce gain at the frequency of the parasitic, two things
>should be done. First, the internal feedback path must be neutralized,
>and second, the external feedback path (plate to cathode or output to
>input) must be broken or at least impeded. The external path can be
>disrupted by either shunting the undesired frequency to ground, or by
>selectively routing undesired frequencies to a higher-impedance path.

No, the undesired frequency must be dampened with degeneration or
dissipative loading that reduces the gain at the oscillation frequency.
The remaining (suppressor loaded) gain must be less than the amount
of regenerative feedback.

>The typical L/R parasitic suppressor attempts to do the latter, but
>because many types of amplifier tubes can oscillate over a fairly wide
>range of frequencies, the network must have a relatively low Q.

That's correct. But the circuit parameters affecting this Q are too complicated to explain without drawings.

What it boils down to is keeping the anode lead short and wide between the tube and the tuning capacitor, mounting and grounding the tuning capacitor as near the tube as possible and to the same sheet metal to ground all the RF grounds (including the grids). That lets you use the lowest value of R, and values between 30 and 150 ohms almost always work fine for the tubes amateur power levels require. Finally the resistor must be the dominate thing in the anode to tank path at the frequency where instability occurs. That requires a low reactance in series with the R, and a high parallel reactance shunting the R.

>is moderately effective at suppressing the undesired frequency band,
>but because of the compromise between bandwidth and Q, the
>suppressor cannot provide significant loss to the undesired
>frequencies without also introducing loss to signals within the desired
>range.

That's why I suggest using tuned suppressors if the tube oscillates near the operating frequency, shunt L / series C suppressors if the tube oscillates at moderate distances from the operating frequency, and a conventional suppressor if the tube oscillates a good distance above the operating frequency.

Try your calculations again for a suppressor like this...Put a coil in series
with the anode lead. Connect a capacitor in series with the suppressor resistor and connect that across the coil. Now the current shift to the resistor happens twice as fast, so the loading goes up at the square of the frequency ratio, instead of at a linear rate. In other words, with the

coil in parallel with the R, the current shift from the coil to the R is linear, doubling the freq. will only double the circuit loading by R.

If I have a series RC circuit paralleling the suppressor's coil, the capacitive reactance can be used to decrease the impedance of the path through R as the normal suppressor coil's reactance increases with frequency. The loading increases twice as fast as with the basic suppressor, and fundamental current through the lossy R is reduced!

You can model or calculate the effects of a series RLC circuit resonant near the parasitic frequency placed in parallel with the regular suppressor coil. In severe cases you could even parallel tune the conventional coil while series tuning the dissipating RLC path at the parasitic frequency.

>The situation with 811A's is somewhat different, insofar as the
>undesired frequency band is relatively narrow due to the upper
>frequency limit of the tubes. Therefore, increasing the Q of the
>suppressor may be an effective means of reducing loss on desired
>frequencies, as well as providing additional attenuation of undesired
>oscillations.

Actually the "undesired frequency band" is usually pretty narrow with all tubes. There is usually a narrow range of frequencies where instability occurs. Remember the grid resonance *usually* dominates the frequency of the oscillation, and the anode resonance must *usually* match the grid for a problem to occur. So if we just dampen the anode at the frequency where the grid "floats", we will usually be OK. Some tubes (like 8877's) won't ever oscillate if the grid is grounded correctly no matter what is done in the anode.

>Rather than constructing a L/R network that exhibits 23 ohms at 30
>MHz and 50 ohms at 60 MHz (see previous calculations), why not
>increase the value of the resistor significantly (or eliminate it
>altogether), decrease the inductance of the suppressor coil, and add a
>capacitor across the coil sufficient to achieve a high Q L/C
>suppressor?

Because that won't suppress at all. There would be little or NO dampening loss! That would actually make it worse, because now the anode would be free to "wiggle all around and tickle the grid". You've just made an unloaded TPTG oscillator!

>By way of example, say that we eliminate the resistor from the
>suppressor, then reduce the coil from 6 turns to 3 turns (0.032 uH).
>This will reduce the XL at 30 MHz from 24 ohms to only 6 ohms. If
>a 220 pf capacitor is now paralleled with the coil, the network will
>resonate at 60 MHz. Assuming a (conservative) Q of 10, the parallel
>resonant impedance at 60 MHz will increase from 49 ohms to
>approximately 120 ohms.

I doubt if the LC network Q would be that low. But it certainly would if the LC network were loaded with a 100 ohm resistor! Anyway, even 100 ohms of series XL on 30 MHz has a negligible affect on the 10 meter performance. The problem is really keeping the lossy R out of the circuit on 30 MHz, and keeping it in the circuit at 60 MHz or so.

>To go a step further, the half-power bandwidth of the suppressor
>would be approximately 6 Mhz, with significant suppression of
>undesired frequencies extending a considerable distance beyond that
>range. If the bandwidth *had* to be increased, a parallel resistor
>could be added, bearing in mind that it will reduce the impedance to
>undesired frequencies.

We don't want impedance, we want resistance at the undesired frequencies. We want a "pure impedance" at the desired frequencies, since that is non-dissipative. We just can't have that impedance so large it upsets the tank operation or tube to tank coupling excessively.

>BTW, now that I've done these calculations, I understand the fallacy
>of the nichrome. Considering how little impedance difference there
>is in an L/R suppressor between desired and undesired frequencies,
>the last thing the circuit needs is a further lowering of Q.

Yes, and the nichrome is in the path that mostly affects the HF signal, not the parasitic!!!!! What a bunch of hooey!

Subject: Help with Homebrew Plate Choke

jeff@wa1hco.mv.com (Jeff Millar) wrote:

> Please describe the test setup. GDO placement, connections to
> choke, etc.

Hello Jeff,

The homebrew choke is resting on a stack of papers on my desk.
Every time I remove turns, I cut off the excess wire and short the
choke with its own leads.

To roughly locate the resonances, I couple the GDO tightly to the
choke, sometimes placing it inside the form. After each point is
located, I move the GDO coil away from the choke until the dip is
barely perceptible, then re-dip. The coil of the GDO is parallel to the
choke at all times.

Frequency of the readout was verified by tuning the GDO across the
nearest ham band (in this case, 10M) and listening for the oscillator.
I left my receiver tuned to 28.0 MHz during these tests and I checked
the dial accuracy frequently.

Any ideas?

>sounds and changing the delay of the treble sounds.

This is also known as Doppler distortion, and I strongly question whether
whizzer cones suffer because of this, or rather because this type of
tweeter simply can't reproduce high frequencies. Despite assertions by
the "experts", I've never been convinced that this type of distortion is
discernible as "bad". Some of the early planar speakers had a superb

sound quality and only used a single diaphragm to cover a very wide range of frequencies. Also, microphones don't have separate elements for different frequencies - the highs are constantly modulated by the lows. As far as I'm concerned, the only reason to break up the reproducers into different units is to better match the frequency response and power handling capability of each type speaker.

>Nitpicking aside,

Not before I mention that my personal favorite is Transient Intermodulation Distortion. Yeah, that must be the problem with SSB, T.I.M. . . .

>If it matters, the receiver has a broad four-pole crystal lattice filter,

That's why it sounds better. Now, if it only had some output tubes instead of that LM380 . . . <g>

Do you mean that AM sounds better when you listen to a commercial broadcaster using a modern receiver with a 6 KHz xtal filter, or that Amateur AM in the old days sounded better?
I'm asking this because I agree with you, but only as it relates to the old rigs. I think the
difference occurs for two reasons. First, older transmitters (AM) used audio filtering to rolloff the audio outside the 300 - 3000 range. In most cases, the rolloff was *very* slow and still had significant energy outside this band. Second, older AM receivers had a passband much broader than 6 KHz, and with kinder, gentler rolloff than today's filters. I can still remember how bad they sounded on AM, relatively speaking, when the crystal filter (usually only two crystals) was activated. Try this sometime with an SX-28 and you'll see what I mean.

>Perhaps other people disagree, but I'm convinced SSB does not sound as good as an >amateur AM signal. Obviuosly one would not expect it to sound like a commercal AM >signal, where the bandwidth exceeds the 300-3000Hz.

To say that it doesn't sound as good is an understatement. Personally, I find it extremely tiring, which is just one more reason I work more CW than 'phone <g>.

>My thoughts as to a possible explanation are:
>
>1) <snip> Perhaps then the 20Hz to 300Hz information makes the signal sound better.

Yep.

>2) Its very difficult to re-insert the carrier at precisely the correct frequency at
>the receiver. <snip>
>
>3) Perhaps there need to re-inser the carrier at the correct amplitude, or
>in the correct phase. I've never looked at the maths to say if this is true.

I don't think 2) and 3) have a significant impact. As evidence of this, I recall several friends of mine in the 60's who converted their ARC-5 transmitters to DSB and who achieved very respectable carrier suppression. Using a receiver at the time which couldn't even keep 100 Hz accuracy (let alone 10 Hz), I can tell you that the fidelity of their signals was *almost* as good as standard AM.

I'm not gonna touch the broadcasting/telemetry issue. However, why not use procmail and a simple Korn script to have your e-mail forwarded? I have mine trim out who it is from and what the subject is and forward that to my pager. Works great. Got me out of one meeting, already. ;-) But you could just as well forward the entire thing, sans headers other than that needed From: one, if desired.

That way, you don't have to modify anything, don't have to worry about the broadcast/telemetry issue, and it won't cost anything.

Let's take it to e-mail if there isn't enough interest in the newsgroup in this, or it's thought inappropriate. I can send you a copy of my script and the relevant procmail entry in my .procmailrc file if you're interested.

There are a large number of Japanese N-Channel dual-gates that should
substitute very well for this device. Audio service companies use these,
mostly as replacements in FM receiver front ends.

I believe one of the common numbers we used was a 3SK140, but I've
been out of the industry for a number of years. You should be able to verify
a few suitable numbers with a local audio/video technician.

From: john.seboldt@blackboard.com (John Seboldt)
Subject: Bias circuits for solid state amplifiers

From: rohrwerk@netcom.com (John Seboldt)
You mention the bias diode method, and an active regulator method. I
think it would be better to use the active regulator, because less idle
current is drawn. The basic diode method is fine, but you have lots of
current flowing through the series resistor and diode that is not
destined for your transistor bases. It of course has the advantage of
super simplicity. But I think you'll be happier with an active regulator
with an adjustment pot so you can set bias to your liking; you'll get
less wasted DC current to boot. I'll be building up the 140 watt amp kit
from CCI, which uses the Motorola AN762 design.

2268. RF Plate chokes

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-30 00:00:00 UTC
From: Waltk@pica.army.mil
Message-ID: <9505300959.aa15141@COR5.PICA.ARMY.MIL>
Source record: 112574

Hi Jack, I didn't see your initial post, but I'd like to comment
on choke building. I wound my own in a straight, non-pi,
configuration and it had a resonance in the 10M band. I knew that
because it "blew up" when I tried tuning the amp on 10M CW.
I used a noise bridge that only went up to an R of 300 and
noticed a resonance near the 10M band. I first removed some
turns but it had little effect on the resonance. So, I rewound
the choke in a pi configuration, using W1FB's design in the 1987
ARRL handbook as a guide, and the resonance moved just outside the
10M band, somewhere in the "upper channels" of the CB band.
Moving it this slight amount did the trick. I feel that
the resonance you see at 33 Mhz should be sufficiently far
enough (> 10%) away to be OK.

The only sure fire way to test a choke "in circuit" is to
tune the amp and if it explodes you need to move the
resonance out of the band of interest. Recently, I acquired
the Autek RF-1 analyst which will measure an R up to 2000 ohms.
With this device it should be a snap to find a resonance
"in circuit" and avoid the other (blow'em up) method to test
for resonances. The reactance of a RF choke is quite high and
thats why its difficult to get a null on the RX using an RF
noise bridge (like the Palomar) that only goes to 300 ohms.

Wish you luck in your building endeavours.

>"broadcast" use) the operative requirement is intellgibility. Without the big I

Well, I was waiting for someone to make that point, actually. In military
communications especially (with which I have a couple of decades of experience)
intelligibility is *all* that matters. Personally, I feel the same about
ham gear, but others may not - in fact, I'm sure there are hams who are searching for
fidelity without regard to intelligibility under poor signal conditions.

My standard for a voice transmitter is "how well does it 'punch through'
under marginal signal conditions," and I take it that you use the same or
a similar benchmark. So, while I did kibitz a bit on the "fidelity" issue
I really regard it as irrelevant in a ham transmitter, but that's probably
due to my military background and the fact that, also being a a former AM/FM
broadcaster, I never regrded ham radio as being a "broadcast" medium (see
related threads on this in r.r.a.p ;-))

Having said that, however, there is no doubt that the diffrence between
military and/or civil emergency comms and ham comms is that the ham can *make
a choice* about fidelity versus intelligibility, whereas the military et al
cannot. So, if you *want* to sound "really spiffy", go for it!

You can try MOSFET's of BF 900 - series,manufactured mainly by
Philips,Siemens and Telefunken. I think that BF 961,963 and 964 are
the best equivalents [suitable for VHF].If you want to try something
above 200 MHz, try BF900,or 960 or 966 [966S is better].

2274. Help on GM Vehicle Computer Data

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-30 00:00:00 UTC
From: allent@mnsinc.com
Message-ID: <3qg5gr$475@news1.mnsinc.com>
Source record: 112580

As an inveterate homebrewer, I am hoping an enterprising ham might also carry over his/her affliction to automobiles and be able to steer me in the right direction.

My apologies if this is the wrong group or off-topic, but I would appreciate info or a steer to source of information regarding 1988 & later GM computer data from the Electronic Control Module (ECM) and Asembly Line Diagnostic Link in my 1988 Chev G20 Van.

What I am seeking is the scheme or protocol for the single serial data ALDL signal line which provides digital data regarding the output of various vehicle sensors and the ECM's commands to control engine operation. The cheapest instrument in my area runs over $350.

Although I can read the individual wire terminals to the ECM with a digital multimeter adn interprete them with help of the Service Manual, there must be a reasonably simple way to capture the data via the ALDL and the serial port of a PC. Ideally someone has already cobbled together some Visual Basic code so the outputs could be read real-time. Any Popular Electronics articles on this?

Any info would be appreciated, particularly if you could shoot me an e-mail.

Many thanks.

Dave Allen, WA2BSL

<snip>

This sounds entirely plausible to me. Unfortunately, I don't have either
a general-coverage generator, or anything similar to the MFJ analyzer.
I think I'm going to have to let this one go and rely on being able to
build a continuous-winding choke. This brings up another question . . .

At one point, I had the 1" diameter choke wound with 80 turns of #26, for a
total winding length of about 1-1/2". The only resonance near the ham bands
was at 33 MHz. With a calculated inductance of 82 uH and resistance of
0.82 ohms, the Q of the choke at 30 MHz calculates to more than 18,000.
Given this number, do I need to worry about the 33 MHz resonance? Will
in-circuit operation broaden the response, or is 33 MHz far enough removed?

I actually did once try measuring the impulse response of the Collins
mechanical filters, and it was so incredibly nasty that I just packed
the whole project in. You've never seen so much ringing in your life...

How about a transformer feedback amp? I don't know the noise figure, but
it's supposed to be low. The topology is a common-base amp with
transformer feedback from the collector to the emitter.

I don't have an original reference, but Rohde included a push-pull version
in one of his receiver articles in QST. (I think the one where he reviewed
the design of a Rohde and Schwarz transceiver.)

Dallas Lankford has been writing about them in the newsletters of the US
medium wave DX clubs: the NRC's "DX News" and the IRCA's "DX Monitor".

Does anyone have a reference for the original paper or any tutorials on
this kind of amp?

>Subject: Component Values for Parasitic Suppressors?

>The original capacitors are .0047 disc ceramics with *very* short
>leads. To these I added 100 pf discs with even shorter leads.

100 pF may only be a change at high VHF, and not at HF or low VHF.
With the 100 pF you may have been better with long leads, so the cap
was series tuned at the parasitic frequency!

>When you say "multi-layer chip", are you describing leadless
>capacitors?

You can get them with leads. The main point is to avoid adding an
unwanted parallel resonance from the grid to the chassis. That would
aggravate instability (like the grid chokes in parallel with the grid
bypass caps in the TL-922 and SB-220 do).

>If so, I would worry that the stress of inserting and removing the
>tubes would eventually break the capacitors. These aren't the type of
>sockets that have pin holders riveted to the ceramic - the pins in
>these are free to move side-to-side like sockets for receiving tubes.

That is a problem, but you could add a flexible lead as short and as
wide as practical to eliminate the breaking problem.

>Regarding the resonant frequency of the caps, doesn't the 60-70 MHz
>limit of the tubes allow the luxury of *moderately* greater lead
>lengths than would be the case for tubes like 3-500Z's?

Ahh, that's a very good point you brought out. You've got a good
understanding of the problem!

What you say is true. But I was giving the easiest explanation and the
best "general rule". So while you probably can be a good bit less
careful with the 811's external grid lead lengths because they are so
LONG in the tube already, I wouldn't make that a habit for other tubes.
Better to make it a safe general statement that won't get someone else
in trouble.

>The ideal suppressor coil would have a very high Z at the frequency
>of the parasitic, and no appreciable R or Z at the operating
>frequency to prevent a loss of harmonic suppression and tank Q.

Read it this way...The ideal suppressor COIL (not the whole
suppressor, just the COIL) would have a very high Z at the frequency
of the parasitic. The COIL would have no appreciable INTERNAL
R (and minimal Z) at the operating frequency to prevent a loss of
harmonic suppression and tank Q. In other words the coil would look
infinitely large at the parasitic frequency, and like an absolute short
at
the operating frequency. I'm not talking about the entire suppressor,
just the coil of the normal suppressor. A resistor must still be in
parallel with this coil, or there will be no VHF dampening.

>In order to reduce gain at the frequency of the parasitic, two things
>should be done. First, the internal feedback path must be neutralized,
>and second, the external feedback path (plate to cathode or output to
>input) must be broken or at least impeded. The external path can be
>disrupted by either shunting the undesired frequency to ground, or by
>selectively routing undesired frequencies to a higher-impedance path.

No, the undesired frequency must be dampened with degeneration or
dissipative loading that reduces the gain at the oscillation frequency.
The remaining (suppressor loaded) gain must be less than the amount
of regenerative feedback.

>The typical L/R parasitic suppressor attempts to do the latter, but
>because many types of amplifier tubes can oscillate over a fairly wide
>range of frequencies, the network must have a relatively low Q.

That's correct. But the circuit parameters affecting this Q are too
complicated to explain without drawings.

What it boils down to is keeping the anode lead short and wide
between the tube and the tuning capacitor, mounting and grounding the
tuning capacitor as near the tube as possible and to the same sheet
metal to ground all the RF grounds (including the grids). That lets you
use the lowest value of R, and values between 30 and 150 ohms almost
always work fine for the tubes amateur power levels require. Finally
the resistor must be the dominate thing in the anode to tank path at the
frequency where instability occurs. That requires a low reactance in
series with the R, and a high parallel reactance shunting the R.

>is moderately effective at suppressing the undesired frequency band,
>but because of the compromise between bandwidth and Q, the
>suppressor cannot provide significant loss to the undesired
>frequencies without also introducing loss to signals within the desired
>range.

That's why I suggest using tuned suppressors if the tube oscillates near
the operating frequency, shunt L / series C suppressors if the tube
oscillates at moderate distances from the operating frequency, and a
conventional suppressor if the tube oscillates a good distance above the
operating frequency.

Try your calculations again for a suppressor like this...Put a coil in
series
with the anode lead. Connect a capacitor in series with the suppressor
resistor and connect that across the coil. Now the current shift to the
resistor happens twice as fast, so the loading goes up at the square of
the frequency ratio, instead of at a linear rate. In other words, with the

coil in parallel with the R, the current shift from the coil to the R is
linear, doubling the freq. will only double the circuit loading by R.

If I have a series RC circuit paralleling the suppressor's coil, the
capacitive reactance can be used to decrease the impedance of the path
through R as the normal suppressor coil's reactance increases with

frequency. The loading increases twice as fast as with the basic suppressor, and fundamental current through the lossy R is reduced!

You can model or calculate the effects of a series RLC circuit resonant near the parasitic frequency placed in parallel with the regular suppressor coil. In severe cases you could even parallel tune the conventional coil while series tuning the dissipating RLC path at the parasitic frequency.

>The situation with 811A's is somewhat different, insofar as the
>undesired frequency band is relatively narrow due to the upper
>frequency limit of the tubes. Therefore, increasing the Q of the
>suppressor may be an effective means of reducing loss on desired
>frequencies, as well as providing additional attenuation of undesired
>oscillations.

Actually the "undesired frequency band" is usually pretty narrow with all tubes. There is usually a narrow range of frequencies where instability occurs. Remember the grid resonance *usually* dominates the frequency of the oscillation, and the anode resonance must *usually* match the grid for a problem to occur. So if we just dampen the anode at the frequency where the grid "floats", we will usually be OK. Some tubes (like 8877's) won't ever oscillate if the grid is grounded correctly no matter what is done in the anode.

>Rather than constructing a L/R network that exhibits 23 ohms at 30
>MHz and 50 ohms at 60 MHz (see previous calculations), why not
>increase the value of the resistor significantly (or eliminate it
>altogether), decrease the inductance of the suppressor coil, and add a
>capacitor across the coil sufficient to achieve a high Q L/C
>suppressor?

Because that won't suppress at all. There would be little or NO dampening loss! That would actually make it worse, because now the anode would be free to "wiggle all around and tickle the grid". You've just made an unloaded TPTG oscillator!

>By way of example, say that we eliminate the resistor from the
>suppressor, then reduce the coil from 6 turns to 3 turns (0.032 uH).
>This will reduce the XL at 30 MHz from 24 ohms to only 6 ohms. If
>a 220 pf capacitor is now paralleled with the coil, the network will
>resonate at 60 MHz. Assuming a (conservative) Q of 10, the parallel
>resonant impedance at 60 MHz will increase from 49 ohms to
>approximately 120 ohms.

I doubt if the LC network Q would be that low. But it certainly would if the LC network were loaded with a 100 ohm resistor! Anyway, even 100 ohms of series XL on 30 MHz has a negligible affect on the 10 meter performance. The problem is really keeping the lossy R out of the circuit on 30 MHz, and keeping it in the circuit at 60 MHz or so.

>To go a step further, the half-power bandwidth of the suppressor
>would be approximately 6 Mhz, with significant suppression of

>undesired frequencies extending a considerable distance beyond that
>range. If the bandwidth *had* to be increased, a parallel resistor
>could be added, bearing in mind that it will reduce the impedance to
>undesired frequencies.

We don't want impedance, we want resistance at the undesired
frequencies. We want a "pure impedance" at the desired frequencies,
since that is non-dissipative. We just can't have that impedance so large
it upsets the tank operation or tube to tank coupling excessively.

>BTW, now that I've done these calculations, I understand the fallacy
>of the nichrome. Considering how little impedance difference there
>is in an L/R suppressor between desired and undesired frequencies,
>the last thing the circuit needs is a further lowering of Q.

Yes, and the nichrome is in the path that mostly affects the HF signal,
not the parasitic!!!!! What a bunch of hooey!

Subject: Help with Homebrew Plate Choke

jeff@wa1hco.mv.com (Jeff Millar) wrote:

> Please describe the test setup. GDO placement, connections to
> choke, etc.

Hello Jeff,

The homebrew choke is resting on a stack of papers on my desk.
Every time I remove turns, I cut off the excess wire and short the
choke with its own leads.

To roughly locate the resonances, I couple the GDO tightly to the
choke, sometimes placing it inside the form. After each point is
located, I move the GDO coil away from the choke until the dip is
barely perceptible, then re-dip. The coil of the GDO is parallel to the
choke at all times.

Frequency of the readout was verified by tuning the GDO across the
nearest ham band (in this case, 10M) and listening for the oscillator.
I left my receiver tuned to 28.0 MHz during these tests and I checked
the dial accuracy frequently.

Any ideas?

This is also known as Doppler distortion, and I strongly question whether whizzer cones suffer because of this, or rather because this type of tweeter simply can't reproduce high frequencies. Despite assertions by the "experts", I've never been convinced that this type of distortion is discernible as "bad". Some of the early planar speakers had a superb sound quality and only used a single diaphragm to cover a very wide range of frequencies. Also, microphones don't have separate elements for different frequencies - the highs are constantly modulated by the lows. As far as I'm concerned, the only reason to break up the reproducers into different units is to better match the frequency response and power handling capability of each type speaker.

>Nitpicking aside,

Not before I mention that my personal favorite is Transient Intermodulation Distortion. Yeah, that must be the problem with SSB, T.I.M. . . .

>If it matters, the receiver has a broad four-pole crystal lattice filter,

That's why it sounds better. Now, if it only had some output tubes instead of that LM380 . . . <g>

>a redection in quality.

Do you mean that AM sounds better when you listen to a commercial broadcaster using a modern receiver with a 6 KHz xtal filter, or that Amateur AM in the old days sounded better?
I'm asking this because I agree with you, but only as it relates to the old rigs. I think

the
difference occurs for two reasons. First, older transmitters (AM) used audio filtering to rolloff the audio outside the 300 - 3000 range. In most cases, the rolloff was *very* slow and still had significant energy outside this band. Second, older AM receivers had a passband much broader than 6 KHz, and with kinder, gentler rolloff than today's filters. I can still remember how bad they sounded on AM, relatively speaking, when the crystal filter (usually only two crystals) was activated. Try this sometime with an SX-28 and you'll see what I mean.

>Perhaps other people disagree, but I'm convinced SSB does not sound as good as an
>amateur AM signal. Obviuosly one would not expect it to sound like a commercal AM
>signal, where the bandwidth exceeds the 300-3000Hz.

To say that it doesn't sound as good is an understatement. Personally, I find it extremely tiring, which is just one more reason I work more CW than 'phone <g>.

>My thoughts as to a possible explanation are:
>
>1) <snip> Perhaps then the 20Hz to 300Hz information makes the signal sound better.

Yep.

>2) Its very difficult to re-insert the carrier at precisely the correct frequency at
>the receiver. <snip>
>
>3) Perhaps there need to re-inser the carrier at the correct amplitude, or
>in the correct phase. I've never looked at the maths to say if this is true.

I don't think 2) and 3) have a significant impact. As evidence of this, I recall several friends of mine in the 60's who converted their ARC-5 transmitters to DSB and who achieved very respectable carrier suppression. Using a receiver at the time which couldn't even keep 100 Hz accuracy (let alone 10 Hz), I can tell you that the fidelity of their signals was *almost* as good as standard AM.

: : >

I'm not gonna touch the broadcasting/telemetry issue. However, why not use procmail and a simple Korn script to have your e-mail forwarded? I have mine trim out who it is from and what the subject is and forward that to my pager. Works great. Got me out of one meeting, already. ;-) But you could just as well forward the entire thing, sans headers other than that needed From: one, if desired.

That way, you don't have to modify anything, don't have to worry about the broadcast/telemetry issue, and it won't cost anything.

Let's take it to e-mail if there isn't enough interest in the newsgroup in this, or it's thought inappropriate. I can send you a copy of my script and the relevant procmail entry in my .procmailrc file if you're interested.

Maybe Jack's on to something here...has anyone characterized the impulse response of a typical SSB sideband reject filter...what do the overshoots from fast wavefront voice peaks do to the following stages?

There are a large number of Japanese N-Channel dual-gates that should
substitute very well for this device. Audio service companies use these,
mostly as replacements in FM receiver front ends.

I believe one of the common numbers we used was a 3SK140, but I've
been out of the industry for a number of years. You should be able to verify
a few suitable numbers with a local audio/video technician.

>What is the best printed circuit board (PCB) program
>for the PC for less than $500? Is BoardmakerII a good program?

I use "Easy PC", It sells for well under $500 and works great !!! It does not "Autoroute" the board though. You lay it out yourself. Not a problem for anything less than a moderately complex PCB.. They have autorouting programs but are expensive, take a lot of computer and lots of computing time to resolve, after you have entered the entire schematic in to the system. Another feature call "schematic capture" is available on many systems including Easy PC. It will draw a schematic as you draw the PCB, and automatically update the schematic as you make changes to the board layout. Even with this feature, Easy PC is still much less than $500.

All of my semeconductor cross referances say to use the
ECG222 MOSFET-N channel transistor as a replacement for the
old RCA type # 40673.
also the Thompson SK3065/222, Workman WEP905/222, and old GE MRO
GE-FET-4 are listed as replacements.

2281. ESCUCHA RADIO INTERNET EN ESPANOL

PARA LOS RADIOAFICIONADOS HISPANOS EN INTERNET

RADIO INTERNET EN ESPANOL

A todos los radioaficionados hispanos que lean este E-Mail los invitamos a escuchar RADIO INTERNET EN ESPANOL que se transmite por esta red. Para hacerlo solo sigan las instrucciones y si tienen cualquier consulta escriban a miglia@ix.netcom.com.

EL TERCER PROGRAMA DE RADIO VIA INTERNET ESTA YA ON LINE, ESCUCHELO.

Tal cual lo programado a las 11:59 PM del Sabado 27 de Mayo fue colocado en nuestro FTP el tercer programa de Radio en Espanol Via Internet y como ya se volvio casi custumbre los radio escuchas comenzaron a bajarlo solo pasados algunos minutos de la media noche. Es notable ver desde que remotas latitudes hay latinoamericanos que ingresan a disfrutar de esta experiencia, nunca pensamos que nuestra gente estaba repartida por toda la tierra como lo esta. A todos muchas gracias por escucharnos y aqui algo de informacion:

Programacion Radio Internet en Espanol

051495.ra Primer Programa Tema Central "Internet Phone" Como Hablar Via Internet (New HF)

052195.ra Segundo Programa Tema Central "Videoconferencia Via Internet"

052895.ra Tercer Programa Variedad de Temas y Demostracion Internet Phone

Espanol.ra Archivo formato .ra para test

Leame.txt Este archivo

SINTONICE RADIO INTERNET EN ESPANOL YA ESTAMOS TRANSMITIENDO VIA LA RED

Si ahora es posible escuchar radio via Internet y nosotros pensamos que sera esta la nueva opcion que reemplazara las antiguas y ruidosas transmisiones de onda corta.
El proximo domingo 14 de Mayo comenzaran las transmisiones de los PROGRAMAS DE RADIO EN ESPANOL VIA INTERNET, dichos programas estaran disponibles en el FTP de nombre FTP.NETCOM.COM en los directorios /pub/mi/miglia y bajo el nombre correspondiende a la fecha de emision, por ejemplo este domingo 14 de mayo el file conteniendo al programa se llamara 051495.ra

FTP: FTP.NETCOM.COM
DIRECTORIO: /pub
SUBDIRECTORIO: mi

SUBDIRECTORIO: miglia
FILE: 051495.ra

PARA ESCUCHAR NUESTRO PROGRAMA DE RADIO EN ESPANOL VIA INTERNET

Para poder escuchar nuestro programa de radio en espanol debera contar con un software llamado RealAudio Player, una PC con Windows 3.1 y una tarjeta de audio. RealAudio lo podra obtener "SIN CARGO" dentro de Internet en:

http://www.realaudio.com/

Cuando este comunicado con esta pagina seleccione:
"donwload your own copy of the RealAudio Player"

Y siga las instrucciones completando la forma correspondiente con sus datos personales, las caracteristicas de su computador y por ultimo el tipo de cuenta en internet que esta usted utilizando. Esto lo ayudara:

A. Ingrese todos sus datos personales
B. Internet Connection = PPP
C. Provider = Por ejemplo NI.NET
D. Speed = 14.400 Baud
E. Machine and Sound = 486 DX2 66MHZ - Windows 3.1 - 8 MB - 340 MB Disco
F. Coloque su nombre el principio del PRE-REASE AGREEMENT

Completada esta informacion RealAudio le enviara de inmediato via
E-Mail un numero de registracion y un password. Con estos datos entonces regrese a http://www.realaudio.com/ y efectue el download del programa RealAudio Player.

1.- El programa obtenido (RealAudio Player) tendra un nombre similar a raplay07.exe.
2.- Ejecutelo colocando el comando raplay07.exe y ENTER.
3.- Este programa al ejecutarse genera un directorio de nombre RAPLAYER.
4.- Dentro de ese directorio encontrara el programa pnclient.exe que es el que utilizara para escucharnos.

Ahora bien para obtener nuestros programas de radio ingrese como ANONYMOUS al siguiente ftp:

FTP: ftp.netcom.com
DIRECTORIO: \pub
SUBDIRECTORIO: mi
SUBDIRECTORIO: miglia

O sea: ftp.netcom.com/pub/mi/miglia

Como Operar pnclient.exe desde Windows:

- Ejecute pnclient.exe
- Habra con el mouse el cuadradito superior izquierdo
- Selecciones Load...
- Seleccione Local File
- Con la ayuda de Browse... busque el file del programa con terminacion .ra en

su disco y seleccionelo.
- Oprima OK y disfrute de nuestros programas.

ESCUCHE CADA DOMINGO NUESTRO PROGRAMA DE RADIO EN ESPANOL VIA INTERNET
EL 21 MAYO TRATAREMOS COMO TEMA PRINCIPAL "VIDEOCONFERENCIA O TRANSMISION DE VIDEO COLOR VIA INTERNET CON UNA PC Y WINDOWS" FILE 052195.ra

Nota: A los 1.050 usuarios de internet que nos escribieron respecto a nuestro programa de radio, gracias.

George Migliarini
E-Mail: miglia@ix.netcom.com

2282. HABLAR VIA INTERNET Si ahora es posible

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-05-31 00:00:00 UTC
From: miglia@ix.netcom.com

ESTAN LAS BANDAS DE HF DESAPARECIENDO ?

Los amantes de las comunicaciones tienen ahora otra modalidad disponible y se trata de INTERNET PHONE, si asi como lo leen ♦Hablar via Internet♦ este sera el fin de las bandas de HF o solo un reemplazo cuando las condiciones de propagacion no nos ayuden. Para hablar por internet solo siga las instrucciones y les recomendamos escuchar nuestros programas en espanol de RADIO INTERNET EN ESPANOL, para ello busque mas informacion de como hacerlo aqui mismo o escriba a miglia@ix.netcom.com

Por ultimo los que tengan Internet Phone listo y operativo les regamos nos lo hagan conocer a nuestro E-Mail. Gracias.

AHORA PODEMOS HABLAR POR TELEFONO VIA INTERNET PHONE

Es dificil de creer pero miles de usuarios estan hablando via la red INTERNET y si usted tambien quiere hacerlo aqui le damos toda la informacion necesaria para poder realizarlo y contestamos algunas preguntas tambien:

Pregunta: Cual es el costo para poder hablar via INTERNET PHONE
Respuesta: Ni un centavo mas de lo que paga actualmente por su cuenta

Pregunta: Se escucha claro
Respuesta: Lo mismo que una llamada telefonica internacional

Pregunta: A donde puedo hablar via INTERNET PHONE
Respuesta: A cualquier parte del mundo

Pregunta: Con quien puedo hablar via INTERNET PHONE
Respuesta: Con cualquiera usuario de internet que este On Line y tenga INTERNET PHONE

COMO HABLAR VIA INTERNET

Para poder hablar por telefono via Internet hay que tener los siguientes elementos:

486 PC Computer
8 MB RAM
Windows 3.1
Winsock 1.1 compatible TCP/IP y coneccion a internet 14,400 baud modem (SLIP/PPP)
Tarjeta de audio compatible con Windows
Programa Iphone (Demo o version registrada)

Si esta confundido con los terminos TCP/IP y SLIP/PPP consulte con quien le da su servicio internet y pregunte si su cuenta reune estas condiciones. Respecto al programa Winsock 1.1 o compatible esta dispoble sin costo via Internet. Ahora bien la tarjeta de audio debe reunir la condicion de ser Windows compatible como el caso de Sound Blaster por ejemplo. Por ultimo le hara falta el programa IPHONE el cual lo puede obtener sin cargo en su version demo o pagando por la version definitiva.
Teniendo todos estos elementos usted podra entonces conversar con otros usuarios que esten On Line y que tengan tambien Internet Phone no importando en que parte del mundo esten y lo mas interesante no pagara nada adicional por este servicio solo lo que actualmente esta pagando. Para tener una idea NETCOM ofrece el servicio windows Netcruiser por $19 dolares al mes con 20 horas prime time y free el resto, esta cuenta reune las condiciones para utilizar IPHONE. Con Netcom no hace falta Winsock 1.1 esta ya incluido.

Para obtener IPHONE Demo (Sin Cargo) ingresar a:

http:///www.vocaltec.com/

Hacer el download del programa y seguir las instrucciones, el costo de la version registrada es de $59.00.

IPHONE Vocaltec Inc. (201) 768-9400 o E-Mail info@vocaltec.com

For Winsock Trumpet send E-Mail to tech-support@trumpet.com.au o busque que hay muchas versiones sin cargo en internet como por ejemplo ftp.utas.edu.au

LA CALIDAD DE LA VOZ VIA IPHONE ES CLARA LOS ESPERO ON LINE PARA CHARLAR

Try using an SK3050 or a ECG221 in place of an old RCA 40673.

<snip>

This sounds entirely plausible to me. Unfortunately, I don't have either
a general-coverage generator, or anything similar to the MFJ analyzer.
I think I'm going to have to let this one go and rely on being able to
build a continuous-winding choke. This brings up another question . . .

At one point, I had the 1" diameter choke wound with 80 turns of #26, for a
total winding length of about 1-1/2". The only resonance near the ham bands
was at 33 MHz. With a calculated inductance of 82 uH and resistance of
0.82 ohms, the Q of the choke at 30 MHz calculates to more than 18,000.
Given this number, do I need to worry about the 33 MHz resonance? Will
in-circuit operation broaden the response, or is 33 MHz far enough removed?

73,

Jack WB3U

I actually did once try measuring the impulse response of the Collins
mechanical filters, and it was so incredibly nasty that I just packed
the whole project in. You've never seen so much ringing in your life...

****

Date: 30 May 95 13:59:56 GMT
From: Waltk@pica.army.mil
Subject: RF Plate chokes

Hi Jack, I didn't see your initial post, but I'd like to comment
on choke building. I wound my own in a straight, non-pi,
configuration and it had a resonance in the 10M band. I knew that
because it "blew up" when I tried tuning the amp on 10M CW.
I used a noise bridge that only went up to an R of 300 and
noticed a resonance near the 10M band. I first removed some
turns but it had little effect on the resonance. So, I rewound
the choke in a pi configuration, using W1FB's design in the 1987
ARRL handbook as a guide, and the resonance moved just outside the
10M band, somewhere in the "upper channels" of the CB band.
Moving it this slight amount did the trick. I feel that
the resonance you see at 33 Mhz should be sufficiently far
enough (> 10%) away to be OK.

The only sure fire way to test a choke "in circuit" is to
tune the amp and if it explodes you need to move the
resonance out of the band of interest. Recently, I acquired
the Autek RF-1 analyst which will measure an R up to 2000 ohms.
With this device it should be a snap to find a resonance
"in circuit" and avoid the other (blow'em up) method to test
for resonances. The reactance of a RF choke is quite high and
thats why its difficult to get a null on the RX using an RF
noise bridge (like the Palomar) that only goes to 300 ohms.

Wish you luck in your building endeavours.

Some of us have been lucky enough to play with receivers using IF
DSP's. When you have available highly adjustable digital IF Bandpass
filters, digital demodulation, and one Hertz tuning steps, SSB sounds
like a guy talking across the table (given a decent multi-thousand
dollar transmitter.) In just 5 or 10 years, when IF DSP technology is
affordable on any decent receiver, we will look back on this discussion
and laugh about the good ole days...

I don't know about piping the data into a pc, real time or otherwise but you
can get the info.

Go to a library that carries Mitchel service manuals for your vehicle. I think
it's the emission controls book that tells how to extract computer codes.

I don't remember the details but all you need is a piece of wire to short two
of the terminals and the check engine soon light will flash. Reminds me of
Morse code but you just need to count the flashes. flash......flash..flash
would be one then two which is a code twelve. If I remember right means
there are no error codes stored in the computer. I think it's the bottom row,
two rightmost terminals that you connect with the ignition on, then when done
turn off the ignition then remove the wire.

This technique only gives any error codes that are stored in the computer. There is no telling how old they are but the Mitchell books explain what all of the codes are and how to find the source of the problem. I used this technique with great success in tracking down a bad ignition coil that a regular mechanic and the local GM dealer couldn't locate on my '86 Pontiac GrandAm. I was a little irate after changing 6 fuel injectors and another $50 part that I can't remember the name of for what turned out to be no reason thanks to the advice of my friendly GM dealer. From now on I'll get off my lazy butt and with alittle help from a Mitchell book, my multimeter and I will do just fine and save a few bucks too...

The technique described may not be correct as it is recalled from my fallable memory but I recall that it worked on my '86 GrandAm and on a '82 Olds Cutlass Cierra. The methods may vary on other GM's and what each code means would almost certainly vary from model to model. I'm not saying to do anything, I'm just saying what worked for me so don't get upset with me if you do something that I did and your onboard computer ends up looking like the federal building in OK City.

happy diagnosing and 73

Here's a list I made up a few months ago. You can still get dual-gate MOSFETs, but they ain't cheap. It might be easier to look up an equivalent ckt that doesn't use one of these. I don't have a Japanese FET book, so I don't have specs for any of the 3SKs, so I dunno whether they'd make a good 40673 substitute.
-Tom R. N1OOQ randolph@est.enet.dec.com

Dual-Gate MOSFETs
==========

These are still available for a price, even the old standby 40673. The bargain MOSFETs these days are:

Type	Price	Where
3SK39	$1.33	MCM Electronics
3SK73	1.52	MCM Electronics
3SK74	1.95	RF Parts
3SK45	2.70	RF Parts
NTE221	2.85	Ckt Specialists
3SK72	2.93	RF Parts
3SK51	3.25	MCM Electronics

Also available:

Type	Price	Where	Type	Price	Where
3SK73	$3.73	RF Parts	3N212	5.95	RF Parts

Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Now I know these rigs are just great the way they are ! I may get some people upset at the thought of changing originals but I am new to this equipment and don't want to miss out on anything ! Anyone have any neat mods for these ? Also let me take this time to thank all who helped in the purchase questions on the R390/R390A. As you can see I came up with a nice deal on a R390A (ok but but dead 11 & 25 mhz) and a spare for parts as well as a CV-157 SSB adapter minus the meters and a few tubes. The 157 had a number of problems but mostly minor. It now has one dead channel but I are working an that. I still have to get a 390 manual to look at the band problems but that should not be too bad. Fixing these are half the fun ! Thanks in advance for any reply. 73's N1DVE

The most popular mod is to remove the ceramic bypass capacitors on the
AC power line. This will make it more sensitive to hash on the power line
but will reduce your chances of getting killed. These capacitors invariably
become leaky over the years and the chassis starts floating at voltages that
you may find alarming.

Another popular mod is to replace the ballast tube with a resistor. Don't
do this. 'Nuff said.

There is a very good audio output section modification in a recent issue
of Electric Radio. The improvement in sound quality is astonishing. It
came out about a year ago.

Let me also point out that in standby mode, the voltages on the PTO tubes
are somewhat higher than they ought to be. Someone who could develop
a mod to remedy this would definitely be helpful.

These are very fine units. The 390A is a real pain to work on, but is
a spectacular performer.

Let me know how you liked the CV-157 and if there are any more where it
came from! I'd love to have one.

> I speak only for myself... >>>>>>>>>>>>>>O<<<<<<<<<<<<<

I don't know the devices you have in your amp, but from what I gather, some devices will not run in class AB. Most of these are in fact many transistors in one package, all in parallel. However, for class AB, you need resistors in each leg to equalise the individual devices. Same is true for class C, but not so much. Hence a device designed for class C, may blow if run class AB. You need higher value resistors for class AB. Clearly limiting the standing current will help, but it will not be very linear. I think a number of published designs in amateur circles get away with it, simply because they are really running close to class C, with insufficient standing current. Hence they proiduce high levels of 3rd and 5th order IM products.

I would be inclined to speak to Motorola. You might find out the hard way the devices are not suitable for high power class AB.

I dont suppose thats what you wanted to hear, but be careful!

Subject: help hf antenna

Hi All...

I live in an apartment and need some ideas for a low profile 80-10m ant.
Of course ir I'm going to get back into hf the ant. will have to perform well.
Alot to ask? I'm sure it's been done and done well. I have a small deck to work with.
Approx. 13'x7'. I do have a clothesline there now that does a diagonal. My wife is
at her limit with the vhf ant.s on a mast out there now so low key is important.
I have an excellent location (about 1300').
Thanks for all your help in advance. Please email me.

How about a transformer feedback amp? I don't know the noise figure, but
it's supposed to be low. The topology is a common-base amp with
transformer feedback from the collector to the emitter.

I don't have an original reference, but Rohde included a push-pull version
in one of his receiver articles in QST. (I think the one where he reviewed
the design of a Rohde and Schwarz transceiver.)

Dallas Lankford has been writing about them in the newsletters of the US
medium wave DX clubs: the NRC's "DX News" and the IRCA's "DX Monitor".

Does anyone have a reference for the original paper or any tutorials on
this kind of amp?

<snip>

This sounds entirely plausible to me. Unfortunately, I don't have either
a general-coverage generator, or anything similar to the MFJ analyzer.
I think I'm going to have to let this one go and rely on being able to
build a continuous-winding choke. This brings up another question . . .

At one point, I had the 1" diameter choke wound with 80 turns of #26, for a
total winding length of about 1-1/2". The only resonance near the ham bands
was at 33 MHz. With a calculated inductance of 82 uH and resistance of
0.82 ohms, the Q of the choke at 30 MHz calculates to more than 18,000.

Given this number, do I need to worry about the 33 MHz resonance? Will
in-circuit operation broaden the response, or is 33 MHz far enough removed?

I actually did once try measuring the impulse response of the Collins
mechanical filters, and it was so incredibly nasty that I just packed
the whole project in. You've never seen so much ringing in your life...

From: Waltk@pica.army.mil
Subject: RF Plate chokes

Hi Jack, I didn't see your initial post, but I'd like to comment
on choke building. I wound my own in a straight, non-pi,
configuration and it had a resonance in the 10M band. I knew that
because it "blew up" when I tried tuning the amp on 10M CW.
I used a noise bridge that only went up to an R of 300 and
noticed a resonance near the 10M band. I first removed some
turns but it had little effect on the resonance. So, I rewound
the choke in a pi configuration, using W1FB's design in the 1987
ARRL handbook as a guide, and the resonance moved just outside the
10M band, somewhere in the "upper channels" of the CB band.
Moving it this slight amount did the trick. I feel that
the resonance you see at 33 Mhz should be sufficiently far
enough (> 10%) away to be OK.

The only sure fire way to test a choke "in circuit" is to
tune the amp and if it explodes you need to move the
resonance out of the band of interest. Recently, I acquired
the Autek RF-1 analyst which will measure an R up to 2000 ohms.
With this device it should be a snap to find a resonance
"in circuit" and avoid the other (blow'em up) method to test
for resonances. The reactance of a RF choke is quite high and
thats why its difficult to get a null on the RX using an RF
noise bridge (like the Palomar) that only goes to 300 ohms.

Wish you luck in your building endeavours.

Some of us have been lucky enough to play with receivers using IF DSP's. When you have available highly adjustable digital IF Bandpass filters, digital demodulation, and one Hertz tuning steps, SSB sounds like a guy talking across the table (given a decent multi-thousand dollar transmitter.) In just 5 or 10 years, when IF DSP technology is affordable on any decent receiver, we will look back on this discussion and laugh about the good ole days...

I don't think anyone has volunteered to write one. It'd be a rather large task.

You might try the ARRL Handbook and the ARRL book "Solid State Design for the Radio Amateur". I also recommend Hayward's book on RF design, recently reprinted by the ARRL

Amateur Radio Relay League
225 Main Street
Newington, CT 06111
USA
1-203-666-1541

I'm sure the Radio Society of Great Britain also has some excellent publications, although I don't have an address for them.

You can try MOSFET's of BF 900 - series,manufactured mainly by
Philips,Siemens and Telefunken. I think that BF 961,963 and 964 are
the best equivalents [suitable for VHF].If you want to try something
above 200 MHz, try BF900,or 960 or 966 [966S is better].

Subject: help hf antenna

Hi All...

I live in an apartment and need some ideas for a low profile 80-10m ant.
Of course ir I'm going to get back into hf the ant. will have to perform well.
Alot to ask? I'm sure it's been done and done well. I have a small deck to work
with.
Approx. 13'x7'. I do have a clothesline there now that does a diagonal. My wife
is
at her limit with the vhf ant.s on a mast out there now so low key is important.
I have an excellent location (about 1300').
Thanks for all your help in advance. Please email me.

How about a transformer feedback amp? I don't know the noise figure, but
it's supposed to be low. The topology is a common-base amp with
transformer feedback from the collector to the emitter.

I don't have an original reference, but Rohde included a push-pull version
in one of his receiver articles in QST. (I think the one where he reviewed
the design of a Rohde and Schwarz transceiver.)

Dallas Lankford has been writing about them in the newsletters of the US
medium wave DX clubs: the NRC's "DX News" and the IRCA's "DX Monitor".

Does anyone have a reference for the original paper or any tutorials on
this kind of amp?

I actually did once try measuring the impulse response of the Collins
mechanical filters, and it was so incredibly nasty that I just packed
the whole project in. You've never seen so much ringing in your life...

Date: 30 May 95 13:59:56 GMT
From: Waltk@pica.army.mil
Subject: RF Plate chokes

Hi Jack, I didn't see your initial post, but I'd like to comment
on choke building. I wound my own in a straight, non-pi,
configuration and it had a resonance in the 10M band. I knew that
because it "blew up" when I tried tuning the amp on 10M CW.
I used a noise bridge that only went up to an R of 300 and
noticed a resonance near the 10M band. I first removed some
turns but it had little effect on the resonance. So, I rewound
the choke in a pi configuration, using W1FB's design in the 1987
ARRL handbook as a guide, and the resonance moved just outside the
10M band, somewhere in the "upper channels" of the CB band.
Moving it this slight amount did the trick. I feel that
the resonance you see at 33 Mhz should be sufficiently far
enough (> 10%) away to be OK.

The only sure fire way to test a choke "in circuit" is to
tune the amp and if it explodes you need to move the
resonance out of the band of interest. Recently, I acquired
the Autek RF-1 analyst which will measure an R up to 2000 ohms.
With this device it should be a snap to find a resonance
"in circuit" and avoid the other (blow'em up) method to test
for resonances. The reactance of a RF choke is quite high and
thats why its difficult to get a null on the RX using an RF
noise bridge (like the Palomar) that only goes to 300 ohms.

Wish you luck in your building endeavours.

Some of us have been lucky enough to play with receivers using IF DSP's. When you have available highly adjustable digital IF Bandpass filters, digital demodulation, and one Hertz tuning steps, SSB sounds like a guy talking across the table (given a decent multi-thousand dollar transmitter.) In just 5 or 10 years, when IF DSP technology is affordable on any decent receiver, we will look back on this discussion and laugh about the good ole days...

I don't think anyone has volunteered to write one. It'd be a rather large task.

You might try the ARRL Handbook and the ARRL book "Solid State Design for the Radio Amateur". I also recommend Hayward's book on RF design, recently reprinted by the ARRL

Amateur Radio Relay League

You can try MOSFET's of BF 900 - series,manufactured mainly by
Philips,Siemens and Telefunken. I think that BF 961,963 and 964 are
the best equivalents [suitable for VHF].If you want to try something
above 200 MHz, try BF900,or 960 or 966 [966S is better].

2298. IF filter - how to test?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-01 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Jun1.122152.64678@ucl.ac.uk>
Source record: 112603

I've been offered some IF filters at about 91MHz, which will be the first IF in a receiver I'm designing. Trouble is, I dont know either the load resistance or capacitance. Obviously I could make an educated guess and try, but having two variables, theres a lot of combinations! I dont know the full spec - only the pass bandwidth. Are there any less trying ways to determine what these devices want to see? I've got a spec. analyser to use.

davek G8WRB.

Thanks to all of you who replied to my message asking for information to help my son with a QRP rig!! The response was SUPER!!!!! He and I gleaned a lot of good information from your responses. Some of you suggested parts manufacturers. One of his friends had the Mouser and Digi-Key catalogues and leant them to Noel. I'm sure that he will call to get other catalogues. Your suggestions about QRP rigs was also super. He's read the ARRL handbook and the ARRL QRP book. I'm sure that he will request information from some of the kit manufacturers that you recommended. Again, THANKS!!!!

By the way, Noel was 14 in March. He's been busy learning electronics by doing a lot of reading lately. We also have a Radio Shack 200-in-one kit and he's been building circuits to see how they work. He's been reading schematics and even modifying ones that he's seen to build his own. In fact, he showed me one when I went home for lunch today!! On a different note, He got his Tech Plus license back in Feb. of this year. Just last Saturday, He got his General License!! (Dear-old-Dad just got his Tech Plus last Saturday.)

Again, THANKS A LOT for all the quality replies!!!

From: n1ist@netcom.com
Message-ID: <n1istD9IHtD.Eu0@netcom.com>
Source record: 112613

I just got off the phone with Ten Tec. Looks like after a year of
'it will be ready in 4-6 weeks', they have finally realized that it
wont. They have pulled the model 1220 2M kit from the market and
cancelled all orders for it. They plan to re-introduce it whenever
they get the changes in. Turns out it needed more than just a voltmeter
to align it, and they will redesign it to simplify the alignment
process. No, they won't send out kits to those of us with the
service monitors or nice labs at work :-)

In all fairness, the other Ten Tec kits that I have built have all
gone very well. At least they care enough to put a good design on the
market, unlike that other radio kit company...

And before I get all the mail asking, their phone number is
615-453-7172 (info) or 800-833-7373 (orders).

Date: 1995-06-01 00:00:00 UTC
From: tantonr@aol.com
Message-ID: <3qli5n$eco@newsbf02.news.aol.com>
Source record: 112615

Hi there!

I am having a small amount of difficulty with the 903 XVTR. Have built 1296, 2304, 3456 all with no problem, but this little sucker REFUSES to put out enough to drive the mixers (SBL1X type), which is a required +14dBm for two. I've tried a buch of differnt things- have gone over the PCB with a microwave milliwattmeter, and a Simpson 260, etc. All I can get (after some mods, mind you) is +4 DBM out of the final amplifier after the filters. Steve at DEM has been as helpful as he can, but I hate to keep calling him all the time.

Has anyone else had a problem with this, and what am I doing wrong? The PCB is built perfectly acording the the manual, and MMIC voltages are FB.

Any Ideas?

2311. Re: 1296 Mhz cavity help.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-02 00:00:00 UTC
From: Jim Potter <jpawi@roadrunner.com>
Message-ID: <3qm0bn$cne@tierra.santafe.edu>
Source record: 112471

Coupling at the anode is fine. It will have a lower rf voltage than the voltage max point, but all this means is a bit more coupling capacitance. Of course, this won't work if the first voltage minimum is at the tube anode connection, but if the tube is rated for 1300 MHz or so you should be OK. It's really hard to make a capacitive coupler that moves with the sliding short. A better alternative is to inductively couple with a loop that moves with the short. There are problems with that also, if the desired plate load resistance is low.

You probably can do without the trim capacitance. No point adding extra at 1296 MHz. Just remember to keep adjusting the sliding short to compensate for changes in tuning as you adjust the output loading. As a practical matter, once you get close, you can use the output coupling capacitor as the trim. Just peak the rf power output by adjusting the coupling. This works because the tuning is more critical than the impedance match.

The same considerations apply to the cathode end, but the VSWR (impedance transformation) is not as critical since you can adjust the match at the driver. A little VSWR is not a big deal if the transmission line is not too long.

Three signs of too low load impedance. 1.) Grid current is low, 2.) power doesn't change a lot (that's a bit subjective) with plate voltage, and 3.) efficiency is low. (Efficiency also depends on transit time factor and you can't expect good efficiency at the upper limits of the tubes operating range.) Signs of too high plate impedance: 1.) High grid current, 2.) Power increases fairly rapidly with plate voltage, 3.) abnormally high efficiency (see comment in 3 above), and 4.) high voltage sparks at the plate (internal or external) or voltage max point on the plate line. It's better to start with the load impedance too low.

Note on efficiency. You can expect the normal efficiency to be on the order of 30% at the upper frequency limit claimed by the manufacturer. Varian makes some planar triodes (I'm most familiar with the YU-141 and Yu-176) that have such close spacing that they can achieve 60% efficiency at 432 MHz. Don't know what they do at 1296.

2312. LNA for GPS (GaAsFET's vs. MMIC's)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-02 00:00:00 UTC
From: kirk@sdd.hp.com
Message-ID: <3qnole$nnd@news.sdd.hp.com>
Source record: 112472

I posted this to sci.electronics, but the response has not
been huge, so I'll try here...

I am thinking about building a GPS receiver from scratch
to learn more about this kind of stuff. After looking
in HP's Communiucations Components data book, I was
convinced that the best performing LNA to put at the
base of an antenna would be made from a couple of discrete
GaAsFET's (like the HP ATF-10170) instead of a MMIC,
assuming I do the layout properly. Anyone disagree with
this assessment.

Also, could someone point me to some good reference materials
on designing (layout, supply isolation, etc.) 1.5 GHz receivers.

Once I figure all of this out, I'll post the results just in
case anyone is interested.

Thanks for your time!

Now I know these rigs are just great the way they are ! I may get some people upset at the thought of changing originals but I am new to this equipment and don't want to miss out on anything ! Anyone have any neat mods for these ? Also let me take this time to thank all who helped in the purchase questions on the R390/R390A. As you can see I came up with a nice deal on a R390A (ok but but dead 11 & 25 mhz) and a spare for parts as well as a CV-157 SSB adapter minus the meters and a few tubes. The 157 had a number of problems but mostly minor. It now has one dead channel but I are working an that. I still have to get a 390 manual to look at the band problems but that should not be too bad. Fixing these are half the fun ! Thanks in advance for any reply. 73's N1DVE

2314. INFO WANTED: Long Wire Antennas

Newsgroup: rec.radio.amateur.homebrew

Hi! The name here is Jeff, callsign VE3QED. I am looking into putting up a long-wire antenna, or some sort of antenna that I can 'wrap' around my house, rain gutter, or fence. You can make the call.

I need the antenna to service both 160m and 80m, so I figure a 1/4-wave of 160m (131.2 feet/40 meters) would work ok (since that would be 1/2 wave for 80m).

My question is, can the long/random wire antenna simple be fed from my MFJ949E (which supports tuning of random wire antennas) and wrapped around the perimeter of my house? Is this the best way to do it? I do not want the antenna visible so just under the rain gutter (or in it!) would be ok with me. Again, you make the call!

Thanks in advance!

Jeff

Can't help unfortunately - I got two by talking nicely to the sales rep
at work and giving him an order for several hundred quid for other bits
at the same time so he managed to get me a couple. I have a suspicion
they were acquired from AD as 'samples' because they arrived in separate
parcels (a single 44-PLCC in a package about 18 inches long by about
four square :-))

Subject: Digest Problems

Hi gang.
I get Ham-Homebrew in digest form. I have been having a problem lately and am wondering if anyone else is. Today I got Issue 162 of the digest. Embedded inside was Issue 161. Embedded inside Issue 161 is Issue 159. In other words I received three issues in one digest. Is this normal or have I just been lucky? What's the scoop?

Sorry for taking up the bandwidth with my problems...

From: allent@mnsinc.com (David Allen)
Subject: Help on GM Vehicle Computer Data

As an inveterate homebrewer, I am hoping an enterprising ham might also carry over his/her affliction to automobiles and be able to steer me in the right direction.

My apologies if this is the wrong group or off-topic, but I would appreciate info or a steer to source of information regarding 1988 & later GM computer data from the Electronic Control Module (ECM) and Asembly Line Diagnostic Link in my 1988 Chev G20 Van.

What I am seeking is the scheme or protocol for the single serial data ALDL signal line which provides digital data regarding the output of various vehicle sensors and the ECM's commands to control engine operation. The cheapest instrument in my area runs over $350.

Although I can read the individual wire terminals to the ECM with a digital multimeter adn interprete them with help of the Service Manual, there must be a reasonably simple way to capture the data via the ALDL and the serial port of a PC. Ideally someone has already cobbled together some Visual Basic code so the outputs could be read real-time. Any Popular Electronics articles on this?

Any info would be appreciated, particularly if you could shoot me an e-mail.

Many thanks.

I wouldn't worry too much about the drive unless it drops below, say,
8 dBm. An SBL-1 will still work with about 4 dBm, maybe even less.
Maybe not optimally, but not bad enough to cut the output by 6 to 9 dB.
Remember, 50 mW is the absolute maximum power the SBL-1X is rated
for--I'd assume this is the sum of the applied powers. They are
designed for a nominal 7 dBm each.

: PCB with a microwave milliwattmeter, and a Simpson 260, etc. All I can
: get (after some mods, mind you) is +4 DBM out of the final amplifier after
: the filters. Steve at DEM has been as helpful as he can, but I hate to
: keep calling him all the time.

Perhaps you have an oscillation that is causing the amplifiers
to generate power that is removed by the filter(s).

I've built up three of these boards--two of them obtained many years
ago via WA3ETD/SHF systems and one to verify the artwork the ARRL Tech
Department sends out. All seem to work just fine, within the limits of
the design. You could reduce the spurious output even further by
shielding the filters better--I've considered making a three board
design and connecting the shielded modules with SMA connectors...
Maybe after I find another source of cheap SMA panel mount jacks...

2322. 1296 Mhz cavity help.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-02 00:00:00 UTC
From: Conrad Farlow <conrad@g0ruz.demon.co.uk>
Message-ID: <885687035wnr@g0ruz.demon.co.uk>
Source record: 112619

I have recently got hold of a cavity amplifier using a YD1336 tube.It
was used in TV service up to frequency of 854 Mhz.I have read two
articles on cavity amplifiers one by Buzz Miklos WA4GPM and the other
by Russ Miller N7ART.The YD1336 is a triode and I am
waiting for a circuit diagram of the PSU but it would
appear that the grid is biased and the cathode was
grounded.The grid is very adequately bypassed with
regard to rf however.
I have calculated the nominal impedance of the lines and also taken
into account the capacitive reactance of the tube
elements and I have determined that the Anode will tune
to 3/4 wavelengths and the input line to 5/4
wavelengths.The input connector position is fully
variable so no problems there either.However I have
conflicting information about where to take off the rf
from the anode line.The articles above recommend
capacitive coupling and say it should be at voltage
maximum,ie 1/4 wavelength up from the cold end of the
anode line.However the output coupling is currently at
the top of the anode cavity near to the tubes anode
collet.Also there is a sliding short but no fine
tuning(ie a tuning cap in the form of a disc on the end
of a brass screw),should I add one?I am tempted to close up the
original and add my own coupling arrangement 1/4 wave up from where I
think the cavity will tune but I am unsure about what to do.Has anyone
any suggestions?Also what is the best indicator of
correct loading on this kind of amplifier?I will be
monitoring grid current as these tubes have an absolute
max of 5mA grid and I am hoping to run mine with rather
less than 1mA.Any help will be appreciated.

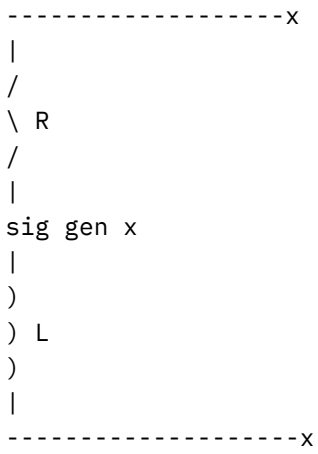
>Anyone have a schematic that I can build to test the values of various
>inductors that I picked up recently? Thanks.

There are a number of ways to do this. A quick and dirty method that will work for inductors that aren't too large or too small is as follows:



R should be a mid-range non-inductive resistor, and L is the unknown inductor. Feed an AC voltage from the signal generator to the series connected R and unknown L. Measure the voltage across R and across L with a high impedance RF voltmeter, a scope works good too. Let V1 be the voltage across R and V2 be the voltage across L.

X=R*V1/V2

X is the reactance of the coil at the frequency of the signal generator. Now use the inductive reactance formula and solve for L.

L=X/(2*pi*f)

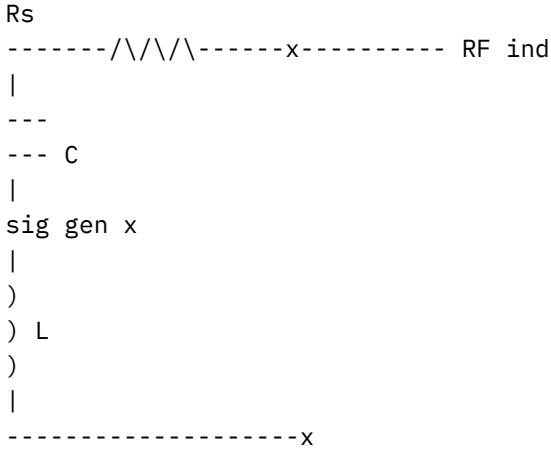
There you have it. The disadvantage of this method is that you have to have a way to accurately measure RF voltage.

Another simple method is to parallel the coil with a known value capacitor. Use a grid dip meter to find the resonance of the LC combination. The reactance of L and C are equal, but of opposite sign at resonance. Given the frequency and known capacitor value, you use the formula for capacitive reactance to determine the capacitor's reactance at resonance.

X=1/(2*pi*f*C)

That's also the inductor's reactance at resonance, so plug that number into the inductance formula given above, and you have the inductance of the unknown coil.

Here's a third method.



Rs should be large, on the order of 100k or more. To use this method, sweep the generator until a sharp dip in indicated RF is found. Then plug that value into the above equations as f and solve as in the grid dipper case. The advantage of this method is that the RF indicator can be a relative reading device of little intrinsic accuracy, and coupling to the circuit is well defined, unlike in the grid dipper case.

There are various LCR bridge circuits that can also be used, but they are more complex than these simple methods. If built carefully, they will have fewer strays, and give a more pronounced indication at the balance point. Their dials can also be calibrated to read out directly in inductance without need to resort to formulas. See the Handbook for designs.

>I am looking for the alignment procedeurs commonly used when setting up
>4 & 6 pack cavities for 2 meters... Either the down an dirty quick ways
>or the step by step methods usually used in tweaking in a set of duplexors.
>Any info would be appreciated

Here's a quick and nasty method. All you need is a pair of HTs, one with an S meter, a step attenuator, an inline pad, and a terminator.

Terminate the Tx port, put a HT on the antenna port through the inline pad, and hook the other HT to the Rx port through the step attenuator. Now transmit with the HT on the antenna port at the repeater's *transmit* frequency. Adjust the Rx notches for minimum signal on the Rx port HT, adjusting the step attenuator as necessary to keep a midscale reading on the HT S meter. Now switch to the repeater Rx frequency and peak any bandpass elements of the Rx cavities for max signal to the HT on the Rx port, again adjusting the step attenuator as necessary to keep the reading at midscale (note, you'll probably want to operate the HT on the antenna port at it's lowest power setting during this adjustment). Iterate back and forth between these two sets of adjustments for the best Tx frequency rejection combined with the best Rx frequency pass.

Now switch the HT and attenuator from the Rx port to the Tx port and terminate the Rx port. Go through the same procedures with this set of cans, except reverse frequencies, IE peak the bandpasses with the repeater Tx frequency and dip the notches at the repeater Rx frequency. Iterate as needed for the best combination of notch and pass.

You can now measure the insertion loss of the pass and reject elements by noting the setting of the step attenuator for a midscale reading on the HT then replacing the cavities with a jumper cable and readjusting the step attenuator for the same reading. The difference in step attenuator readings is your insertion loss. Combining the numbers for insertion loss for the Tx port to antenna and antenna to Rx port at the receiving frequency of the repeater gives the isolation in dB between Tx and Rx. It should be 100 dB or better to prevent desense. The insertion loss from Tx to antenna on the repeater Tx frequency should be low, under 3 dB, and similarly, the insertion loss from antenna to Rx port at the repeater Rx frequency should be low, under 3 dB.

Now you would be finished if the antenna presented a 50 ohm non-reactive termination at the two frequencies, and if the Tx and Rx presented 50 ohm non-reactive impedances at their respective frequencies. But of course they won't. So more work is left to be done. The reactance presented by the antenna feedline must be absorbed into the Tx and Rx cavities immediately adjacent to the antenna connection. The reactance presented by the transmitter must be absorbed into the cavity immediately adjacent to the Tx port. And the reactance presented by the receiver must be absorbed by the cavity immediately adjacent to the Rx port. Note: if the *real* part of the impedance on any of these ports strays far from 50 ohms, you'll need to work on the antenna, Tx, or Rx as appropriate to solve that problem. Tweaks to the cavities will only absorb the reactive part of the impedances.

So hook up the repeater in operating configuration and put an inline wattmeter at the antenna port. Key up the transmitter and make slight adjustments to the pass element of the Tx cavity nearest the Tx port and the Tx cavity nearest the antenna port for maximum indicated forward power.

Now hook up a SINAD meter to the receiver output and feed its tone to one of the HTs on low power and terminated in a dummy load, and probably shielded in a metal box as well. What you want is a noisy signal in the receiver. Inhibit the repeater Tx and carefully adjust the pass elements of the Rx cavities nearest the antenna and the Rx port for best SINAD.

Now let the transmitter key up. Unless you're very lucky, the SINAD reading will drop. Now slightly tweak the reject notches nearest the Tx port and Rx port for best SINAD. Now slightly tweak the notches nearest the antenna for best SINAD. If you've done everything right, you shouldn't see any drop in SINAD now with the repeater Tx on or off. You're done.

Gary

> great 10m conversion.
>
This dino undoubtedly has 2 banks of crystals to produce the 23 channels
(actually 24 with #24 blocked out by the channel switch). If you
look inside you'll doubtless see 2 rows of crystals fairly close to
the channel switch: one bank with 4 crystals and another with 6.
To get the full 23/24 channels to 10M, you'll have to choose whether
to replace the 4 crystals or the 6. It's been years since I've done
this and am too lazy to cross the yard to the shack to look up the
CB SAMs Photofacts but as I recall replacing the 6 crystals is the best
bet for getting usable channelization in the 10M band, though of course
replacing the 4 in the smaller bank will get all 24 channels onto 10
with less money involved.
I'll post you again in a few, if I have a SAMS that covers your Tram
I'll get you to give me your address so I can send it to you. It is
fairly painless (except for buying the crystals) to install them and
touch up the alignment transmit and receive to get the power and rx
sensitivity up to spec. Whether it's worth $20 or higher to buy the
necessary xtals when one can buy later model SSB synthesized CB's that
require only 1 crystal to convert is up to you. Another thing you can
use the existing CB for AS IS is as an exciter/driver to a VHF/UHF
or even another HF band transverter.

2326. Help: Baycom decode problem

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-03 00:00:00 UTC
From: a00074@alumni.laurentian.ca
Message-ID: <1995Jun3.105648@alumni.laurentian.ca>
Source record: 112482

Hi all.

I am in the process to try to install a baycom tnc that I purchased from a fellow ham. I am told it is in working condition and I believe it is.

I do have one problem with though. I cannot decode any transmissions coming from the radio. Reading the manual, I am told that one adjustable resistor should control the voltage on pin 7 of the TCM3105 and that in order to be able to decode anything, the voltage to that pin has to be exactly 2.7volts. However, when I attempt to adjust the resistor from its minimum value to its maximum value, the voltage fluctuates between 1.9v and 2.3v. I believe this is the source of the problem but don't know how to get the voltage to be increased to the pin.

I am no techie by any stretch of the imagination but if I am gently nudged in the right direction with any suggestion, I hope to get this tnc going in no time flat. I do not wish to part with it as it seems to work ok. I am sure it is something right underneath my nose that I am missing.

I am using a MOCOM 35 and all other tests (voltage at the db9 pins are ok, radio transmits ok, my packets are decoded by other stations) seem ok.

Thank you for any help provided and I can be e-mailed at

a00074@alumni.laurentian.ca

>
>De Tom
>
Step 1: get a network analyzer...

Be aware that all adjustments are INTER|ACTIVE!

Cables between the cans are a PRECISE length!

Unused ports MUST be terminated by a GOOD 50 ohm load.

Most systems trade some passband loss for better isolation.
(Expect 2-3 db loss in the passband on both sides [TX & RX])

External adjustable coupling loops are next to Godliness!

If you haven't guessed by now, DON'T touch the cavities!
You probably don't have the experience or proper equipment.
Those modern monitors are NOT good enough to do the right
job on cavities even though they have a tracking generator
to work with the spectrum analyzer.

O.K. The cavities are already messed up, what now?
Use your H.T. into a SWR meter into the TX port of the cavities.
Place an appropriate power meter at the antenna port.
You need to adjust for the best NOTCH at the recieve frequency,
while getting an acceptable (3db or less) bandpass at the transmit
frequency, while maintaining a good SWR at both ports.
Easy no? All of this ASSUMES the cables are the right length,
and quality.

Now, do this with reversed frequencies for the recieve cavities.
Trivial no?

Seriously! Don't fool with the cavities, if you have to ask,
(No insults intended!) your NOT the right guy to tweek them!

Finally, be Darn sure you don't mess up all your work by tightening
the lock nuts etc... without watching the network analyzer.

And yes, you CAN trade hours even days of careful work with simple test equipment for the RIGHT test equipment.

You're looking at apples and oranges. Yes, present techniques won't
let us use 56kb on HF, but that's not the point. We *can* send 60WPM
error free through a 63 Hz bandwidth with presently realizable technique.
That's 2 to 3 times better than most Extras can achieve on CW. And,
we can do that using less power and under worse conditions than the
CW operator must have as well.

Please explain! I thought we were limited to 300 baud, or using ASCII
about 30 characters per second. Not great for data, but i remember
that a model 33 Teletype could type about as fast as i could, at least,
in bursts, and that was only 10 cps. Now, 60 WPM means 1 word per second,
and that's 5 cps (maybe 6 if you count the spaces). Not as fast as some
people can type from copy, but comparing this to CW, that's a considerable
improvement, as you well point out. With suitable buffering, that should
work very nicely for comparable purposes. Hmmm...

Now, doing this in a lot less bandwidth than RTTY and error correction,
under worse conditions than CW?? That deserves some explanation!

... More importantly, radio equipment
designed from scratch to be optimized for digital operation can be
of the same order of cost and apparent simplicity as the CW stations
used by those operators.

I studied carefully the R2/T2 pair, and have thought about doing such
for 10m and above (noting that some of the RS birds go in on 2m and out
on 10m) Does that mean it's simple enough to be a QST project, albeit
probably not as easy as a QRP rig?

There must be some problem here i don't get, such as it's in a mode
that we can't use yet in HF... But wait, i might still be able to have
fun with such a device at 6m and above, where we can try out new coding
schemes. Please, tell more, and if you want to UUENCODE diagrams and/or
schematics in some well-known format, i'll even put it in my WWW page for
others to access.

We are limited to 300 baud on our HF bands below 10 meters by 97.305, and on 10 meters we are limited to 1200 baud. However, note well that baud is a technical signaling term, and baud does not have to equal bits per second. It's common to overload a single baud with multiple bits. All modern telco modems do it. I'm not speaking about use of such techniques above, however, since they aren't necessary to get the performance I quoted. The signaling technique I was alluding to was simple MSK. Adding FEC etc would reduce the effective data rate from the raw numbers quoted. Sorry if I didn't separate those two ideas clearly.

The 60WPM figure is for a raw Baudot alphabet without error correction at 45 baud using MSK modulation. The 1.4 Hz/baud figure would apply to any alphabet of course. For example, we are limited to an occupied bandwidth of 1 kHz on the lower HF bands for data transmissions. Using MSK, we could run up to 714 baud in that bandwidth if baud higher than 300 were permissible. Using symbol overloading so that one baud represented more than one bit would increase our effective bps even further, of course. Examples of that sort of thing are QPSK and QAM. Those techniques aren't as parsimonious of spectrum as MSK though when SNR is included in the equation, IE we'd have to run higher power to get the same BER and thus limit frequency reuse to an extent.

Now 97.309(a) limits the alphabets we can transmit on HF to Baudot, ASCII, and ISO646. So we can't use unspecified alphabets on HF. But that does not limit how we generate modulations to transfer those alphabets, IE how we express those patterns of ones and zeros as RF, nor does it prohibit us from using higher level protocols to facilitate the transmission of those alphabets, IE block codes, FEC, etc. Nor does it limit us in what those alphabets may *spell*. For example, we can transmit binary files by UUencoding them into the ASCII alphabet. Being restricted to only 3 alphabets is a burden, but not a serious one. We've had to deal with such limitations on computer networks for years. An 8 bit alphabet would be more natural, but we can live with the limitations of a 7 bit alphabet, albeit with considerable unnecessary overhead.

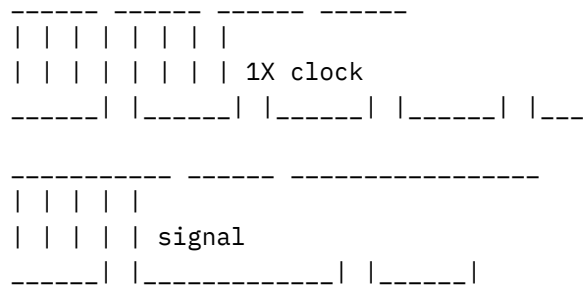
>on 10m) Does that mean it's simple enough to be a QST project, albeit
>probably not as easy as a QRP rig?

Sure. I've seen a number of projects in QST that were far more complex than the GRAPES RF modem (whose baseband is at 10 meters). Note that the GRAPES modem implements MSK, but it isn't the only way to implement MSK, and other circuits could do so with fewer parts, and/or higher performance for HF usage. It is, after all, intended for high speed usage on the UHF spectrum via a transverter, but it does implement the necessary bandwidth conservation techniques, so it serves as an existance proof for the technique.

The transmit modulation generation is simple, but specifically how the demodulator is done ultimately defines the performance of the system. The GRAPES demodulator is done in hardware and optimized for 56 kbaud, so some changes would be required to work most effectively with low rate signals in the noisy HF environment, mainly changes to the IF filter and time constants in the Costas loop. Use of simple DSP would probably make the whole exercise trivial for the baud available at HF. At the time the GRAPES modem was designed, suitable inexpensive DSP chips weren't available to deal with 56 kb and so the design had to be implemented in hardware. That adds circuit complexity that could be eliminated by use of any one of several currently available DSP chips. The GRAPES design is 8 years old, and was intended to be simple, cheap, and easy to build with parts commonly available at the time.

However, the Lowfers have been using low rate codings implemented in hardware for a number of years with remarkable results. They're using effective bandwidths on the order of 0.01 Hz with nothing more elaborate than some opamps, tri-state analog switches, and TTL logic. The key to effective operation is clock synchronization. Once you have that,

correlated oversampling will quickly tighten the effective passband
and rapidly raise the effective SNR. Perhaps a word about this would
be useful. Assume data synchronized to some clock using a simple coding
scheme (a Manchester code in this case).



0 0 1 0 data

A transition of the signal on the falling edge of clock signifies
a 1, no transition on the falling edge of clock signifies a 0.
It doesn't matter which way the signal transitions, only the change
of state matters. The signal always transitions on the rising edge
of clock, thus embedding clock into the signal.

Now if we recover this signal and sample it with a 1X clock, we'll
be looking for the transition on the falling clock edge to determine
if we have a 1 or 0. To resolve that we have to have a fairly high
bandwidth, something on the order of 3X to 5X the clock rate or greater,
otherwise the edges of the signal will be smeared and rounded by the
IF filter and prevent a clear decision. This is undesirable since
it limits the achievable SNR. Adaptive slicers can help a little,
especially for signals that are slewed, but not much.

However, suppose we sample with a high multiple of the clock rate,
say 16x, then we have 8 samples before the suspected transition
and 8 after. If we accumulate these samples and compare their
sums at the end of the bit period, we'll have effectively narrowed
our bandwidth to 1/8th it's previous value with respect to short
duration noise, and we can now use a narrower analog filter with a
bandwidth on the order of 2X clock since a sharp edge is no longer
required to pass in order for the 1 or 0 decision to be made cleanly.

With an even higher oversampling clock, we increase our effective
SNR even more. Now this assumes that the sample time is on the order
of, or less than, the average noise hit. To assure that, we may
have to lower our data rate so that the symbols are long with respect
to noise pulses. But we don't have to narrow the analog filters in
our radio by the same amount to gain the SNR advantage. The sample
and accumulate process has the effect of narrowing the bandwidth
with respect to noise.

Now the GRAPES MSK modem doesn't use this technique, but the Lowfer
system does. It's a fairly powerful technique for low rate signals
that's easy to implement in hardware (it's basically the principle

of a switched capacitor filter, but with the added feature of having
the sample clock locked coherently with the desired signal, and that's
a major improvement). Now, we can extend this same method, or better ones,
there are much better ones, to individual RF cycles if we have sufficient
hardware speed to deal with the high sample clock. Now we have a powerful
technique indeed for separating coherent signals from incoherent noise. The
coherent samples add constructively, but the random noise does not, IE a
rising edge always increments over a series of samples, but the amplitude
of incoherent noise may go down as likely as it goes up at any sample
because of it's statistical nature. Thus it tends to sum to zero, or a
constant bias, over a large number of samples. Foreknowledge of the
phase of the desired signal is one of the most powerful techniques for
separating desired coherent signals from a chaotic channel. It's the
basis for the astounding weak signal performance of the NASA DSN.

>There must be some problem here i don't get, such as it's in a mode
>that we can't use yet in HF... But wait, i might still be able to have

Clover is an existance proof that modulations other than simple FSK
are allowed on HF. It's perhaps more complex than necessary because
it has to work through ordinary analog SSB radios which are very far
from optimized for digital transmission, but the fact that it exists,
and is permissible under the rules, is ample proof that we can use
other modulations for digital data at HF than crude FSK.

By and large, amateurs haven't used more advanced digital modulation
techniques on HF because (a) they don't know about them, (b) they
think they are too complex or difficult to understand, (c) they
believe (falsely) that they are illegal, (d) they're so brainwashed
into the manual Morse and analog voice paradigms of communications
that they reject out of hand better digital methods, and (e) there
have been no commercial Japanese products implementing the techniques
for amateurs to purchase.

As for the GRAPES RF modem, its details were explained throughly
by Dale Heatherington (its designer) in one of the ARRL Computer
Network Conference Proceedings. Look for a paper on the WA4DSY
modem if you want to know more. Again I would note that this serves
merely as an existance proof for the technique. Alternate implementations
optimized for low rate signals would serve better for HF operations.

: Here's a quick and nasty method. All you need is a pair of HTs, one with
: an S meter, a step attenuator, an inline pad, and a terminator.

I've used the Step-attenuator-plus-receiver-S-meter measurement technique
and it can be really useful for a variety of applications. I find
that a couple of step attenuators gives me some very powerful measurement
capabilities if I just calibrate a point or two on my receiver's S meter.

However, there are a few very serious caveats that must be considered,
especially when measuring something like a duplexor.

1. How good is the HT receiver? I bet Gary is thinking of a commercial
grade HT, not the typical amateur transceiver. Many modern ham HTs
will respond to signals away from the indicated receive frequency.
Many times this will not be a problem, but trying to make 80 to 100
dB dynamic range measurements (like when tuning a duplexor) with a
a leaky receiver will be difficult. (And if you do this "at the site"
are there any other transmitters on?)

2. There are enough interactive adjustments on a typical duplexor,
its really easy to get them off into the weeds, frequency response
wise. A simple single-point measurement technique will often not
be enough to get all the cavities tuned to where they need to be.
So there is a big difference between, say, tweaking up a duplexor
that was already tuned to the desired frequency and just needs to
be adjusted slightly and one that is tuned for, say, 463 MHz and
is being moved down to the ham band.

So my suggestion is find someone with a network analyzer, or at least
a spectrum analyzer with tracking generator.

I noticed in the MCM catalog that they have MFE-201s for $1.21 ($0.91 for 10) and MFE-211s for $1.42 ($1.06 for 10). I'm assuming these are the same as the 3N2xx/MPF2xx parts, but my transistor book doesn't list them so I couldn't swear to it. These prices seem almost too good to be true, but I have all the dual-gate FETs I'm likely to need so I haven't ordered any. Their number is 800-543-4330.

Bob, that's fine for rough tuning, but those pieces of equipment
just aren't good enough for final tuning. That's got to be done
at the site with the duplexer hooked up the way it's going to
operate. I've never yet met a real installation where all the
terminations are 50.0+j0.0. The SINAD meter and the inline
wattmeter are the final tuning tools you have to use in every
case to get the duplexer working correctly with the real sources
and loads with which it has to contend.

Anything that will roughly get the duplexer in tune for that
final tweak is good enough, and a couple of HTs, etc are lots
cheaper than a network analyzer or spectrum analyzer and tracking
generator. Sure, I'll use them if they're available. I love high
buck test equipment with lots of knobs and buttons, and they do
make tuneup quicker, but they aren't essential. This is definitely
a case where you can substitute experience for bucks.

2337. Using Surplus YIG Oscillators

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-04 00:00:00 UTC
From: stevem@w6yx.stanford.edu
Message-ID: <3qtbpa$dfa@nntp.Stanford.EDU>
Source record: 112493

I have a pair of YIG oscillators which I recently obtained at the local ham swap. Both units seem to work OK, having applied the appropriate bias, tuning and modulation currents. However, one unit does not work on the lower end of its tuning range until it has warmed up for about 15 min. or so.

Each unit has a pair of heater pins but no markings as to what the voltage or current should be. Is there some standard for this? Perhaps someone can give me a starting point. I have not tried any heater power yet.

One unit is a Systron Donner, the other is a Microsource.

I plan on building sweep generator.

Do be aware that the R-390A and the R-390 have very different schematics. I do have a set of hacks in mine, including a beam deflection tube SSB/CW detector, a modified noise limiter, hang agc, and "0" to 500KHz reception (of a sort.) Alas, I do not have them written up in a form for posting. Howsosomeever, if you are clever enough it is easy to generate these sorts of hacks for yourself with ideas from the ARRL Handbook and old QSTs. You can build the schematic easily enough by tracing the physical sircuitry yourself. That is how I did it until I got my manual. (I even discovered that the ground "bus" input side of the mechanical filters was never grounded to the chassis. Once I grounded it things suddenly came alive and worked the way I expected. I bet that is why I got this beautiful thing surplus looking so clean. - Um this was back in about '69 or so.) Treat your baby with adequate respect and be careful with the mods. It will then do very well for you.

Mumble - 11MHz and 25MHz dead? Schematics are too hard to get at the moment but that sounds like you either need a dose of contact cleaner or you have at least one more band out.... 0.5 - 8MHz the receiver is triple conversion to a variable 17-25MHz first IF. Nope - your two "out" frequencies are not in that overlap band. Check the crystal sockets in the upper oven. These crystals run 11-34Mhz in 1MHz steps for conversion of a 1MHz band to the 3 to 2Mhz range. (Note the inversion.) You probably have the 14Mhz and 28MHz crystals dead or lose or needing pins cleaned. (It IS possible that 430A and 431E are sick, too. Um, I went and got the schematics anyway...) The actual crystal frequencies are half the injection frequencies in some cases. So look for a bad Y409 at 14MHz. That covers both bad bands.)

No - I won't sell my manual on a bet. Nor do I want to pull it apart for copying. There used to be services that sold copies, though. You want

Considering the AJ margin built into the GPS signal and that thermal noise is just another form of jamming fighting noisefigure down to very low levels may be less than rewarding. Do remember that you have 99% of the time interference from at least 3 other satellites "jamming" your desired signal. This can go to as great as something like 7 signals during some intervals. I'd suspect that a 2-3dB noise figure should perform as well as a .1dB noisefigure would. (Heck, 6dB would probably do decently.)

RSGB VHF/UHF Manual has several plans, but some of the active devices may
be difficult to obtain in North America.

Hamtronics in Hilton, N.Y. sells some workable kits. I've built their
435-to-28MHz receive converter for pacsat use, and it works as advertised.
Dual-gate GaAsfet preamp and mixer make it reasonably sensitive.

I just happen to have my HP data book right here...

HPPN Gate Width Optimum Test NFo Ga Package
(um) Freq. Freq. (dB) (dB)
(GHz) (GHz)

ATF-35076 200 4-18 12 0.75 10.5 70 mil ceramic
ATF-35176 200 4-18 12 0.85 10.0 70 mil ceramic
ATF-35376 200 4-18 12 1.0 10.5 70 mil ceramic

These parts are listed as low noise GaAs PHEMT's. The book recommends
that the lowest noise part (35076) be used as the first stage of a
cascaded amplified. The following stages could be any of them.

As far as biasing goes, I'm still learning about that myself.

Hope this helps.

> ATF-35376

These are GaAs FETs. Typical specs, all in dB, Vds=1.5V, Ids=10mA:

ATF-35076 ATF-35176 ATF-35376

optimum NF @ 4 GHz 0.25 0.30 0.40
optimum NF @ 12 GHz 0.75 0.85 1.00

gain @ 4 GHz at optimum NF 16.0 16.0 15.0
gain @ 12 GHz at optimum NF 11.0 11.0 10.0

To make optimum use of these devices, you'll need the S parameters.

Source record: 112503

How about the following dual-gate mosfet? It's a Motorola MPF131
and I have a supply of house numbered critters and have been letting
them go for 3/$1 USofA and charging only $0.55 for postage and handling,
but I don't want to be doing this for a living. I really have a job.
These critters are light, so I think I can get a dozen or so in an
envelope with the critters wrapped in Alum. Foil. I do static protection
steps to keep from zapping them and my source has them in Aluminum foil
lined box. I don't have the facilities or the time to test each one,
but they should be OK. I'm not making anything on this to pay for my
valuable time.

Here are the stats:

Ye Ol Motorola manual says:

MPF131
N-channel Dual Gate MOS Field-Effect silicon transistor

depletion mode transistor designed for VHF amplifier and
mixer applications.

RF amplifier @ 60 and 200 MHZ

Max voltage , drain-source = 25 volts
Max current, drain = 30 ma.
Max power dissipation = 350 mw.

gate 2 ___ drain
<======/ \======>
| |
<======__o/======>
gate 1 source

top view

NOT TO SCALE
(must I tell you)

info above from Kaye Hartman, KD8EK

And in another email I got:

MPF131 - Depletion type dual gate MOSfet with diode-protected gates
Speced as RF AMP @ 60 Mhz and 200 Mhz

Dot on plastic package indicates SOURCE lead, going counter-clockwise
from there: DRAIN, GATE2, GATE1.

Max ratings
Volts-drain-source 25
Drain Current 30 ma.
Ta= 25 degrees C 300 mW (hey its QRP!)

Gate 1 to source cutoff voltage -4.0 vDC
Gate 2 to source cutoff voltage -4.0 vDC
Zero-gate voltage drain current Idss = 3ma min, 10ma typ, 30 ma max.

Forward transfer admittance 8000 umho min, 20,000 umho max
this is biassed at Vds 10vDC, Id=10ma, 1Khz

Ciss = 4.5 pf typ, 7.0 pf max
Coss = 2.5 pf typ, 4.0 pf max
Crss = .023pf typ, .05 pf max (in-circuit capacitance usually larger than this)

Noise figure typ max
60 Mhz 2.5dB 5.0dB
200 Mhz 3.0dB 5.0dB

Power gain (common source)
60 Mhz 20dB 27dB
200 Mhz 17dB 20dB

Used as a R.F. amplifier, Gate 2 is usually set at about 4 v D.C. (unless you
want to apply A.G.C. to it).

This I got from Glen Leinweber.

It may do in a pinch as a replacement and is certainly much cheaper. Only problem:
I have to flatten the leads to get them mailed in an envelope. :-) Again, I don't
want to do this for very long and will do it until the supply runs dry. I don't
take checks and the bank doesn't sell MOSFETs. :-) It's a problem of time
to drive to same, etc. Green stamps OK, but email me first to determine if I am
going to have enough. There are only a few thousand of these still around.
I'm in the callbook.

dit dit

>Jim WB5AOX

I have a similar radio, a "Courier Spartan SSB". I was thinking of using one crystal and making the other oscillator a VFO to cover the Novice portion of the band. Then adding another xtal 500 or so KHz higher would open up some more band coverage. Any possible pitfalls with this? One that I could think of is that trying to span over more than the width of the old CB band may cause a loss of sensitivity and/or output power, since the other filters in the radio are fixed-tuned. It seems like a channelized arrangement would limit what I could hear, or is operation in the 10m band traditionally channelized? Also it would seem that a $1.00 imprecise "microprocessor" crystal with a frequency tolerance of 100ppm would work as well as more expensive custom "communication" crystals since the other oscillator would be variable.

2351. Re: Replacement for 40673?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-05 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <8f6_9506060530@mba.mba.org>
Source record: 112507

I'm not sure who originated this thread, but there have been
various suggestions for replacements for 40673 MOSFET's.

What might be important to note is that the 40673 might not
have magically been a great device, but was used in so
many published projects because others had already used them.
When someobody wanted to build a new project, they'd look
at what others had used, and saw that 40673 in common use,
and decided to use it since it must be good or why was it
already chosen.

I remember my first MOSFET's, and they were not 40673's. I
can't remember if I chose something else because I couldn't
get 40673's or because I wanted to find something cheaper.
I looked in a data book, and there were 40841's that looked
nearly as good. So I used them.

The point to all this is that if you can't get 40673's, maybe
the way to go is look through the catalogs until you find
MOSFET's listed, and then check their specs to find something
suitable, instead of looking in a cross-reference guide and then
trying to find a designated replacement for the 40673.

I came up with an interesting source of MOSFET's just last fall,
though I haven't gotten around to using them to see if they
are good or falsely numbered.

It's in those "FM Boosters" that seem to be readily available.
I'd seen them, and passed them by due to cost. Then I saw them
selling for under two dollars in a couple of places. I bought
one out of curiosity. Figured I'd find a bipolar transistor;
maybe I'd be lucky and find something like a 2N5179. I opened
it up, and found a MOSFET, in the 3N200 series if I recall
correctly. I went back to the store, and bought all that they
had (unfortunately, it was a few days later and some had already
been bought), at a dollar each. Good price for MOSFET's. If
anyone sees these FM Boosters (that's for receive, not xmit!)
at a low cost, it might be worth looking into them.

Ther have been a number of VHF to HF converters (and transverters)
published in QST over the years. My 1994 ARRL Handbook has "Linear
Transverters for 144 and 220 MHz" on page 31-17. You could build
just the receive portion if you wanted.

2355. FET pre-amps and NF

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-06 00:00:00 UTC
From: ae517@FreeNet.Carleton.CA
Message-ID: <D9r2Fn.36y@freenet.carleton.ca>
Source record: 112511

I was planning on building a 10 metre pre-amp from a design in the 1994 ARRL Handbook by Kent Britain. I was hoping to improve my downlink reception for RS-15. The design calls for either a 3sk48, 3sk51 or 3n204 dual-gate MOSFET. The author states that a pre-amp noise figure of 1db to 1.5 db from 28MHz to 220MHz is achievable using the aforementioned devices. These being difficult to find locally, one local supplier suggested an NTE222 as a direct replacement for the 3n204. When I looked at the spec sheet, the NTE222 is described as having a "NF 6dB Max at 200MHz".

This is a far cry from the 1 to 1.5 dB noise figure for which I was hoping. This raises a question:

How is the published NF determined by the manufacturer? Are they referring to noise factor or noise figure? Is noise factor dependant on bandwidth?

In the end, I ended up buying a NTE454, which has a "NF" 1.5 dB less than than the NTE222.

2356. Low-Band DXing errata

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-06 00:00:00 UTC
From: steve@hi.com
Message-ID: <steve-0606951254140001@brainiac.hi.com>
Source record: 112512
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Has anyone else noticed the following error in Devoldere's "Low-band DXing"? It's in both editions.

In the section on single-wire Beverage antenna matching transformers, the book gives the following formula for the number of turns on a toroid for a given inductance:

N = 100 sqrt (L / AL)

(Note that in the second edition, the square-root radical sign is misprinted as a multiplication.)

The formula is correct for AL values in units of uH/100 turns.

The book contains a table containing AL values for several types of toroids and the turns-count for transformers to match to 50 ohm and 75 ohm feedlines. The AL values for the iron-core toroids are given in units that match the formula, but the AL values for the ferrite toroids are given in units of mH/1000 turns. Consequently the turns-count for the transformers that use ferrite cores are too high by a factor of the square-root of 10 (about 3).

Source record: 112513
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Could anyone tell me why toriods are rated in "AL values" such as uH/100 turns, or mH/1000 turns? These "AL values" are often mislabled "units" but do not have the correct dimensions, which are actually inductance/(turns)^2.

Some vendors sell toroids spec'd as nH/(turns)^2, such as Johnson Shop Products, and simple dimensional analysis yields the correct procedure to get the inductance of a coil wound on one of these. Numerically, but not dimensionally, mH/1000 T = nH/T^2, and (1/10) uH/100 T = nH/T^2.

Could anyone tell me why toriods are rated in "AL values" such as uH/100 Given that AL values seem to lead to confusion, such as the typo in Low Band DXing, and are not even dimensionally correct, why is their use so widespread? I seem to recall quite a bit of space devoted to explanation of AL values in one of the license manuals, and also in the ARRL handbook. Perhaps this space might be put to better use.

2359. Re: Component Values for Parasitic Suppressors?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-06 00:00:00 UTC
From: jackl@pinetree.microserve.com
Message-ID: <3r0tcr$34o@misc1.microserve.net>
Source record: 112515

Because of one of Tom's (W8JI) posts, I decided to check the parasitic suppressor resistors that I had previously installed in my oscillating HF amplifier. The resistors were "non-inductive" metal film types, but I nevertheless decided to inspect one, just to see. The resistive element was easily exposed by scraping off the outer layer of paint, and to my surprise, there was a distinct spiral-wound pattern in the body of the resistor.

My next task was to find a few 1W or 2W carbon composition resistors that I could install in the suppressors, and this turned out to be a formidable undertaking. In fact, if anyone reading this hasn't tried to find these resistors lately, you're in for a shock. I must've called twenty or thirty distributors and parts houses looking for these, with no luck. All they had were either carbon or metal film.

Newark, which does show them in their catalog, requires a minimum quantity purchase on 2W resistors that amounts to $50 to $100 worth of a single value. Even at that, there's no guarantee the parts are truly non-inductive. Like Tom says, even some carbon comps are constructed in such a way as to introduce inductance into their design.

For me, the problem's resolved. I stopped at a small, old-time parts house recently, purely by accident, and found a good supply of N.O.S. 82 and 120 ohm, 2W carbon comps. I suspect the only reason these were in stock is that they're an unusual value for most solid state equipment. The owner even said that as he sells them out, he orders replacements in carbon/metal film. Needless to say, I have since broken a few apart, just to be sure they really are non-inductive!

So, if you're reading this and you're into tube-type HF amps, now's the time to stock up on a few of these resistors. Don't wait until they are TOTALLY unavailable. Also, if you do find them locally like I did, don't forget to take a pair of Vise-Grips so you can crack one open and look inside. :)

Thanks for the correction--I really ought to study the details of the
GPS system. It does make sense to provide enough S/N for each signal
so that interference between them isn't a problem.

If all you need is a 4 dB NF, a MAR-6 MMIC at the feedpoint ought to do
just fine. Of course, there are more expensive GaAs devices for even lower
noise figures.

There was a device called a PAL VXO Tuning Monitor. It plugged into a crystal socket of a CB radio to move it between channels, etc. I have two of these. They came in various standard freqs. that fit the crystal being replaced. It was only a matter of changing the crystal, I believe. I have used this with a CB radio and moved it to 10 meters in the manner you describe. It works great and covers the blank spots between channels. Don't forget you have to retweek the RF sections, both transmit and receive. Not hard at all. I have several converted CB radios that I have used on 10 at different times. The one hang-up is there are Uniden and Radio Shack 10 rigs that are as cheap to buy and use as converting a CB. Good luck.

Read up on spread spectrum some more. What happens is any uncorrelated signal is spread out to the greater of the bandwidth of the local estimate of the spread spectrom signal or the signal's original bandwidth. ie a CW signal interfering with a GPS signal would be spread to the original GPS bandwidth while a very broadband noise source would remain a very broadband noise source with some modulation on it that could in theory be recovered using the original noise signal and time delays.

You have data at 50 bits per second riding on the GPS signal that is more or less critical. You have a 1.023 megabits per second chipping rate. This gives you on the order of 1e6/50 or 20,000:1 anti-jam ratio, about 43dB. 7 other such signals at the same level as yours will lower this by a factor of 7 or about 8.5dB. This means that you still have some 34.5dB of anti-jam margin. The jammer can be front end noise as easily as it can be a jammer. This implies noise figure is not "critical".

Since we're talking noise floor of about -204dBW/Hz and an effective bandwidth of 100Hz or so (for roundish numbers) for the data and maybe 10Hz or less for the positioning loop lock we're talking about -184dBW for the data and -194dBW for the position loop. Signals, if I remember correctly, are in the -170dBW range. So you have a VERY healthy carrier to noise ratio in either bandwidth with a "0dB" receiver. A low noise figure helps a bit with vehicle dynamics by reducing "errors" in the data or position loop it has some advantages, particularly with "marginal" receiver designs. But GPS was built to survive some downlink jamming. So any way you cut this analysis you should get decent performance with noise figures even as high as 10dB or 20dB. But in the

interests of an easy receiver design for commercial purposes I suspect 1 or 2dB noise figure is more than adequate. ("Commercial purporses" is a code tracker rather than carrier tracker and is interested in the "advertised" accuracy levels. For differential use the 2dB or better front end is probably well worth it.) (mumble - 1MHz code => 1000' long "chips". 24dB carrier to noise is pretty low so errors on that 1000' is reduced to perhaps 10' or so. *REAL* rough guesstimates here.)

I am in the process of putting together a new HAM 'shack', and I have
come across an interesting 'snag'.

I have heard, many times before, to be sure the HAM radio ground is NOT
grounded to the house wiring ground system. Various explanations follow,
usually to avoid having the house wiring turn into a massive antenna.

Anyways, I was SURE to separate the two and overlooked one point . . .
packet ! My TNC uses a serial cable, connected to my computer, which in
turn has a grounded chassis! Argh! To top it all off, the serial cable
is NOT the right way to ground to a 'secondary' ground. Talk about a
'high' resistance path to ground, forming an 'ideal' ground loop!!!!

My question is, "How can I avoid this, and if I cannot, what effect will
grounding to the house ground REALLY have?" "What are my OTHER options?"

Thanks for your replies in advance,
Jeff

>Perhaps this space might be put to better use.

AL values are favored for the same reason meters per second are favored over furlongs per fortnight. And that reason is that most calculations can be done easily in your head, rather than having to reach for a calculator. As you note, T^2 is already built into the values, so you don't have to do that in your head when using AL values to calculate the number of turns you need for a given inductance.

This is mostly a historical artifact now that all of us routinely have a scientific calculator close at hand. In the manual arithmetic days, it saved a bit of work, and another possible source of manual math error.

Greetings, from a wet Diepenbeek in N.E. Belgium!

Whoever was looking for R390A mods - I suggest you subscribe and / or post a request to the boatanchors list (if you want details, mail me direct). I've seen literally dozens of bits of info on these radios, many, many people on that list have one and there's a LOT of info going. This last week I've even seen that NEW R390(A?) manuals are available from NIST - sorry, but not being a 390 owner, I ditched the postings.

Mail me if you want to know more.

Source record: 112527

After seeing the request posted I checked one of my catalogs and found the company still listed the 40673 MOSFET. Another company is still showing the 3N211, another excellent but no longer available type. I have my own supply in storage but if anybody wants the real thing(s), let me know. I have not called to see what quantities, if any, are still available as it would be a long distance phone call in each case, perhaps without cause but if there is someone needing some it would not be a big deal to find out. Please note; I have no plans to subsidize your hobby so you must include post and COD costs in calculating the final cost. These will tend to be a fixed amount and probably will run around DM15 (Post to me, post to you, COD or bank charges for paying the seller, but the amount can vary, depending on the way the seller wants his money and what sort of postal service is possible. The latter depends in part on the quantity.) If there is a lot of interest and a sufficient supply, some of the costs can be distributed over the various buyers (except for the post to you from Germany!)

This is a potentially dangerous situation. If your amateur gear is totally isolated from AC ground, there couild be a significant difference in voltage potential between the chassis and AC ground. Under these conditions, simultaneously contacting the chassis of the rig and any AC grounded device would place you in the current path.

>usually to avoid having the house wiring turn into a massive antenna.

This will only happen if the feedline radiates due to an improper antenna installation. If this is the case, adding the AC ground as a radiating element probably won't predictably deteriorate your signal any more than the radiating feeder.

>Anyways, I was SURE to separate the two and overlooked one point . . .

Ground all nearby "appliances" together, including the rig. This will avoid the risk of electrical shock and will also serve to reduce the liklihood of ground loops.

Like many folk tales, while there is a grain of truth to this idea in
some *very* special circumstances, it's generally false, not to mention
being a violation of the National Electrical Code.

>My question is, "How can I avoid this, and if I cannot, what effect will
>grounding to the house ground REALLY have?" "What are my OTHER options?"

Ok, this isn't a simple issue, or a single issue. There are several
related concepts and factors involved. Bear with me and I'll try to
touch on most of them.

There are three general reasons given for grounding a station.

1. Improved RF performance.
2. Elimination of stray RF in the shack.
3. Electrical safety.

Of these three reasons, only the latter has merit except under
special conditions. Lets look at them one by one and see where
the truth lies.

1. Improved RF performance.

This is usually a reason claimed for needing a good ground. It is
actually false except with antennas that must work against ground,
and even then the ground needs to be at the antenna feedpoint and
not at the transmitter (unless the transmitter *is* the feedpoint,
as can be true with some random longwire antennas). A balanced antenna,
such as a dipole, yagi, quad, etc, is ground independent. It does not
need a ground connection to work, and will in fact work in free space
with no ground connection present at all. Many verticals, longwires,
and some other asymmetric designs need to work against a ground reference.

That ground reference, however, doesn't necessarily need to be a connection to Earth. A counterpoise, radials, or the like can serve just as well, or better, than an Earth connection. And that connection needs to be under the antenna, and not back at the shack.

2. Elimination of stray RF in the shack.

This is often a reason given for a RF ground connection to Earth. However, this is like taking aspirn for a brain tumor. It may suppress the symptoms to some extent, but it doesn't address the real underlying problem. The real underlying problem is a station design or layout fault. If the equipment has poor Faraday shielding, or if the feeder currents aren't well balanced, or if station interconnections create daisy chains or ground loops, then there will be stray RF in the shack. Grounding one or more cabinets may actually create more circulating currents which can *increase* the problems of stray RF. In some cases, attachment to a good RF ground will reduce stray RF problems at some frequency, but may increase problems at another frequency. This is not the proper approach to dealing with stray RF. The preferred approach is to eliminate the *cause* of the stray RF.

3. Electrical safety.

This is the *real* reason for an effective grounding system for the shack. There are two different hazards that an effective grounding system will solve. One is ordinary electrical shock hazards. In the US, the National Electrical Code is the standard that addresses this. One of the cardinal rules of the NEC is that *all ground connections must be bonded together*. If you fail to do this, you can have a shock hazard between cabinets connected to different ground references. So the myth that you need to keep utility and RF grounds separate is not only false, it can be a safety hazard. (There are a couple of *very* specialized circumstances where the Code permits isolated grounds, but as a general rule, failing to bond all grounds together is a major Code violation.)

The second reason for an effective grounding system is for lightning mitigation. This can be a difficult problem and must be approached with care. A single mistake can be very costly. Lightning is RF, and like any other RF, downlead inductance is a primary concern in setting up a grounding system. Lightning surges also represent peak currents on the order of 8,000 amperes (with ocasional so called "super bolts" going up to 200,000 amperes). These discharges only last for microseconds, so the average power is low, but the peak power is intense. It only takes a slight amount of inductance in a downlead to generate a potential difference of tens of thousands of volts between one end and the other. If these potentials are allowed to express themselves between equipment cabinets, devastating damage can occur to sensitive electronic components.

There are two concepts you must apply to your station ground system as your first lines of defense against these potentials occurring across your equipment. The first concept is that of a single point ground, and the second is called ground window technique.

Single point grounding is simple in concept, but often subtle in execution. Basically, all connections to Earth must be interconnected at a single common point, and all connections from equipment that needs a ground termination must run to that single point and to *no other connection with Earth*. Daisy chained connections are strictly prohibited. Every connection to the single point must be straight and direct from the equipment requiring the ground connection. Ground "busses" are a serious no-no despite their being touted in amateur literature. They form instant ground loops for the equipment, and at the high currents present in a lightning discharge, they can cause thousands of volts to express themselves across the various cabinets connected to the "ground" buss. Don't do this.

The idea here is that because everything is forced to a single potential, that of the single point, *whatever it is*, no current can flow through the equipment. Zero potential difference results in zero current flow. It's those damaging currents you are trying to control. You don't want the path *to* ground to be *through* any of your equipment. Rather, you want the path to ground to be through the single point, and only through the single point. Note well that "ground" is *not* zero volts, and will not *be* zero volts in any sense except a *relative* one during equipment operation or during a lightning strike. This doesn't matter if your layout topology is correct. All "ground" is supposed to be is a *common* potential for everything in the system to reference against. Use of a single point connection *enforces* this single common potential, whatever it may be at any given instant.

When you start thinking about the many "ground" potential interconnections in your station, achieving a true single point ground system seems a daunting task. This is where the related idea of a ground window can help. The purpose of the ground window is to *short out* any possible ground loops in your system at the station entry point.

A ground window is simple in concept, and simple in execution. Basically, it is a physically small conductive plate through which *every* cable that enters or leaves your station must pass. Every cable that is supposed to be at "ground" potential is bonded directly to this plate as it passes through. Every conductor that is not supposed to be at "ground" potential is bonded to the plate via an appropriate suppressor device. (A book could be written on that subject alone.) Then the plate is connected to your single point ground by a heavy low inductance strap conductor. Now any large potential

difference that tries to express itself across cables
connected to various cabinets in your shack will find itself
shorted out at the ground window.

Note carefully that *every* cable must pass through the ground
window plate on its way in or out of your shack. That includes
power, telco, CATV (if present), and any network wiring as
well as the usual antenna feeders, rotator control leads, etc.
If only *one* wire bypasses the ground window, the protection
it offers is lost. Don't run extension cords to power outlets
that don't pass through the ground window. It can cost you
everything you own in a strike, including your life.

Now since you've taken great pains to do this protective grounding
system right, you'll find that it makes an excellent general purpose
RF grounding system as well. This is not to say that you'll generally
need a general purpose RF ground for the shack if you've done your
homework on antenna feeds, Faraday shielding, and the like, but you'll
have one anyway. And if you've done the job right (which requires
attention to a level of detail I haven't fully addressed here), your
station will be able to work even during the worst thunderstorms,
and even during direct strikes, without damage or interruption.
Proper grounding is a specialized, but well understood, part of the
protective process that radio and television stations, commercial
and military two way, and *amateur* radio stations should understand
and apply.

Prom Programming Information Needed:

I have a Kenwood TK701S VHF and and matching TK 801S UHF
transceiver, currently used on 2 meters and 440 respectively.
These originally were commercial units. A thumbwheel channel
selector selects pre-programmed frequencies determined by
ROM chips inside. I would like to build a PROM burner to
program the PLL frequency determining proms. The proms are
old technology, i.e. one time "burn the fuse" types. The proms
are type MC 54730AP, with 32 bytes of memory. I remember
some time back reading that there is a rather tight spec relating
to the amount of current allowed and duration of burn, to burn
each bit. Too little current will cause localized heating on the
chip before opening the fuse, possibly damaging it, and too
much current can cause molten metallized traces to splatter to
other areas of the chip. Anyone have experience in these chips,
and know the spec for burning them? Also, any other equivelant
chip numbers would be of interest.
I also do not know the format for a similar ROM chip which
is in the PL deck inside the radio. This PL chip has a binary
value for each channel, which will cause the PL module to
generate the proper standard PL tone. Anyone out there know
the coding format?

Some of you may not know about "Hambrew" magazine, a new Sprat-size quarterly that is dedicated to homebrewing. I've only seen one issue, but it was pretty impressive: thick, glossy, nice photos, and not just a newsletter. Nice collection of articles, emhasizing QRP, SSB, FM, and more involvement with 6 meters.

What really surprised me was the $10 subscription rate. If you're into home-brew you might want to take advantage of this before they figure out that they have to raise the price. (Also, since the magazine hasn't been around very long, some would-be authors might have a unique opportunity here.)

Their number is (303) 989-5642. Apparently they used to have an 800 number, but that is no more.

Source record: 112536

I am trying to trouble shoot my down east Mode S receive converter but I am not having a lot of luck. The LO is working fine. I am able to see the 564 MHz output on a spectrum analyzer ant it is around 20 Dbm.

I can also find it coming into the converter and to the cathode of the diode in the first stage of the converter. It is my understanding at this point I should see all sorts of harmonics of the 564 Mhz signal but when I probe it with the Spectrum analyzer I only see the 564 Mhz signal, no harmonics at all. As I work my way further doesn't the change I even lose the 564 Mhz signal as it is being filtered out.

I was hoping also that if I didn't have an input signal to the receive input I would see the 2256 Mhz LO signal coming out of the Converter, but no. I've replaced D1 thinking it was open with a 1n4148 (that all I had in a pinch) but results were the same.

ANy clues???

Me:
:Could anyone tell me why toriods are rated in "AL values" such as uH/100
:turns, or mH/1000 turns? These "AL values" are often mislabled "units"
:but do not have the correct dimensions, which are actually
:inductance/(turns)^2.

[...]

:I seem to recall quite a bit of space devoted to explanation
:of AL values in one of the license manuals, and also in the ARRL handbook.
:Perhaps this space might be put to better use.

From gary@ke4zv.atl.ga.us Wed Jun 7 11:18:02 MDT 1995

>AL values are favored for the same reason meters per second are favored
>over furlongs per fortnight.

I'm not sure that's a good example for two reasons: both have the
dimensions of length/time, which is velocity, whereas uH/100 T does _not_
have the same dimension as nH/T^2. And it's not like nH/T^2 is going back
to English units... you still wind up in Henries, so to speak.

>And that reason is that most calculations can be done easily in your head,
>rather than having to reach for a calculator. As you note, T^2 is already
>built into the values, so you don't have to do that in your head when
>using AL values to calculate the number of turns you need for a given
>inductance.

I'm not clear what your point is here. If mH/1000 T is numerically equal
to nH/T^2 (which I think it is... a core of _43_ "mH/1000 T" is also a
core of _43_ nH/T^2) then it takes *exactly* the same amount of
calculation to go from this many turns to that much inductance, and if you
can do one in your head, you can do the other because the 43 (in this
case) doesn't change. (If there are 9 turns, an 81 shows up in both sets
of calculations.) I'd guess there's actually less math, as there's no
extra factor of 1000 (or 100) floating around that you need to square and
divide by, when you use nH/T^2 that you _do_ have to carry around with the
AL values.

>This is mostly a historical artifact now that all of us routinely have
>a scientific calculator close at hand. In the manual arithmetic days,
>it saved a bit of work, and another possible source of manual math error.

Hmmm. First you say it was to avoid "having to reach for a calculator"
and then you say it's "now that all of us have a scientific calculator
close at hand." Again, all I wonder about is the units, not the values, so
the amount of math doesn't change. By discarding "uH/100 T" and "mH/1000

T" and adopting nH/T^2, one gains the benefit of having the units make physical sense, which I would guess lessens the amount of confusion, and the amount of explanation needed to convey their use. (Being versed in dimensional analysis, it took _me_ some effort and head-scratching to understand how to employ AL values "correctly" - and now I read that they're at the root of an enduring typo in a popular book!)

Perhaps they're so widely used because the core-makers persist on using these non-units in their datasheets, and I should bug them and not the readers of this bboard (except possibly the ARRL handbook-editors, etc., here, to whom I submit there is no excuse for propagating physically nonsensical things in technical publications, historical precedent aside).

There should be two separate grounds in the shack - one for the AC
supply and one for RF. Now then comes the confusion, which equipment
should be connected to what. For sure, all the RF output equipment
should go to the RF ground by a low impedance path, and ideally, all
power supplies should be returned to the AC ground. Notice that I
was careful not to say 'equipment chassis' in any of that.

The voltage difference between AC ground and the low impedance RF
ground should be low, maybe a volt or so, but if its higher than
that, check into the cause before doing anything more becauses you
have a potentially dangerous situation.

Take a look at the power cords on your equipment and see which have
3 wire plugs, these will be more difficult to connect to your RF
ground, because by doing so, you have interconnected the AC and
RF grounds.

Interconnecting the grounds may not be a problem in general and
many times you can do it with no ill effects, but be aware that
doing so can cause circulating currents in the whole ground
system which will cause ground circuit noise (result of ground loops).
Separate the grounds often and check for a voltage difference

as a safety precaution. CORRECT THE PROBLEM BEFORE POWERING THE EQUIPMENT.

All power supplies with the output isolated from the chassis should be connected to AC ground only.

Computer chassis are grounded to the AC ground (and good digital design demands that this be only at one point for any one machine. this is why the RS232 interface defines a chassis ground and a separate signal ground. Not all cable manufactures implement this distinction. By convention, the chassis ground is connected to the cable shield and this shield is connected only at one end (usually the computer end). The serial interface card would then handle the signal return (ground) only. This is the way ground loops were handled in the large mainframe computers. You might want to check your computer interface card and your TNC to see what each of them do with pin 1 of a DB25 connector, if it is like the large mainframe implementation, the interface card will ground pin 1 to the chassis and the TNC will leave it open. Signal return will be on pin 7 of the DB25, and a proper cable will not connect pins 1 and 7 together.

All in all, you may have no problem, but you can fix it in your TNC if you have to do it properly. You also could try connecting your TNC chassis to the computer only and not to the rest of your ham gear which would be tied to RF ground. This would give a potential ground loop at the audio interface to the tranceiver, but is not as likely to give problems as one at digital circuits or RF circuits.

Good luck with it,
73,
Don W3FPR

Unfortunately, all terminal manufacturers did not isolate the (interface)
circuitry from the chassis and thus the signal ground (pin 7) was directly
connected to the PE (Protective Earth) bar of the building through the
3 wire power cord. The VT100/VT220 series was particulary problematic
in this respect, with lots of ground potential problems.

No, this is not a sufficient prerequisite. The important thing is what
happens to signal ground (pin 7) inside your PC. This is most likely
connected to the 0 V output voltage terminal in the power supply. To
this point is also connected the signal returns for the monitor and
the signal returns from the printer (and signal ground fom an external
modem). Only if all circuits in all these equipment float in respect to
their respective chasses, only then is it time to worry if the cable
is connected properly.

I very much doubt that you can find a PC installation (computer, monitor,
printer etc..) in which the circuitry floats respective to the chassis and
thus also floats relative to the PE bar in the building (assuming 3 wire
power cords).

A simple solution:
Move the TNC to the computer and take the power from the computer
or from a separate (floating) wallwart. Put audio transformers
(say 600:600 ohms) in the microphone and loadspeaker lines and an
opto isolator for the PTT line. The opto isolator can be omitted,
if both ends of the contact in the PTT relay inside the TNC are
floating. The audio transformer only has to pass 300 - 3000 Hz, so
allmost any audio transformer will do, but if you find a type with
high breakdown voltage specification, it might save your computer
even if your station is damaged during a thunderstorm.

To avoid EMC problems from and to the computer, it is also easier to build
filters for the audio cable than for a high speed serial cable (where you
have to be careful not to distort the waveform).

Anton,

There are a large number of antennas which can be tuned to work
fine without an ATU, at least over parts of the HF bands.
Avoid compact designs with loading coils et.c, they are more
demanding as to tuning.

BTW, a ATU can be made from coax cable and swithes or relays.

Following my request for a low noise, high output intercept amp, Steve Byan suggested transformer feedback and asked for any original references on it.

I have found this:

'High Dynamic Randge Transistor Amplifiers, using lossless feedback'
by Dr. D. E. Norton,
Microwave Journal,
May 1976.

Its a good article, fairly simple to understand and well worth a read. It discusses using both transformers and directional couplers, to reduce gain, increase output intercept while keeping the noise figure constant (all compared to using the active device with no feedback). Using resistive feedback obviously degrades the NF.

I have recently discovered the Motorola MRF-136 has a 1dB noise figure at 175MHz and an output power of 15W, so the intercept should be about +50dBm. However, the test circuit given in the data book at 175MHz uses a stabilising resistor of 27 ohms between gate (its a FET) and earth, which I'm sure wont give the NF I want. I'll contact Motorola and ask if they can give me the circuit which gave 1dB NF.

BTW, many devices are said to be high power and low noise, but the NF and powers quoted are often at different collector (drain) currents, so you cant get both together. Fortunatly, for the MRF-136, both are quoted at the same (I think 500mA) drain current.

Hello again Jeff,

I just realized that you also posted the question regarding the AC ground. The antenna you're planning, in conjunction with the ground system, can be a little tricky.

First, what I said about the AC ground still holds, but this type antenna increases the liklihood of radiation from the chassis of the rig, and therefore from the AC ground.

The problem is that the antenna is fed as an unbalanced radiator right from the output of the (local) tuner. On frequencies at which the feedpoint impedance of the antenna increases, the chassis of the tuner (and therefore the rig) will require a very "strong" connection to RF ground. If a good RF ground is unavailable, the chassis of the tuner and the rig will "float" at a certain RF potential, as will the AC ground.

Rather than disable the AC ground (a practice I consider unsafe), the key is to either provide a good RF ground at the rig & tuner, or use a balanced, rather than end-fed, antenna.

A good RF ground is basically achieved in a multiband situation only by installing a very short cable from the rig to earth ground. The length is required to be shorter as the frequency rises, and for 160-80M, you may be lucky in that regard. BTW, in my experience the gauge of the cable (within reason) will not have a significant impact on the effectiveness of the ground.

This leads to my first question: How long would the cable need to be in order to reach the first available location at which you can install a couple ground rods? My second question is, are you certain you can't install a center-fed dipole, even if it isn't required to be resonant?

Finally, I want to mention that assuming the rain gutter is metal, I would advise against setting the antenna inside it. However, if you are able to inspect the joints of the gutter to ensure electrical continuity, the gutter itself might be a reasonably good radiator. More than a little DX has been worked by hams using pre-existing

structures, and that certainly includes rain gutters. You might want to describe the building itself more fully; things like height above ground, siding and roofing material etc. can be important factors.

Gary,

Excellent article. One question, however: Assuming you bond
everything properly like a reverse daisy chain to a single point gound
at the meter entrance, is it ok to extend that gound by bonding
multiple ground rods together? Something like this

```
Ground Rod --------+ +--------Stuff in shack
| |
Ground Rod ---------+----------+--------Entrance Panel
| |
Ground Rod ---------+ +--------Tower, etc
```

Thanks,

Larry

Gary, this is perhaps the best piece I've ever seen on this topic, particularly considering that it was written within the space constraints of a news post. It is so good, in fact that I've save it for reference, something I seldom do.

I do have one reservation regarding the above paragraph, however. The level of detail you refer to is more properly described as cost of construction. This is the weak link in amateur lightning protection and the reason why most (if not all) amateur installations will never withstand a direct strike, let alone provide operator safety under such conditions.

Anyone who has ever seen a four foot thick concrete base under a commercial FM tower shattered from lightning knows what I'm talking about. There was even an article in the news recently, about a woman who was electrocucted in her bathtub when lightning hit the *underground* water pipes leading to her house.

My point is, in a direct hit, lightning takes *many* paths to ground, not just the shortest or largest cable which we provide. Even assuming that sufficient protection could be guaranteed to the equipment, the operator remains at risk as only a few milliamps are required to stop the heart.

For this reason, barring an expenditure of many thousands of dollars to install protective measures, absolute protection means staying off the air during a lightning storm and disconnecting *all* leads to the equipment. There are no exceptions to this rule.

If heavy gauge solid wire is available, then your inductor problem is
solved, IE you can wind your own. The variable capacitors are a bit
more of a problem. If you are mechanically inclined, and have access
to some sheet aluminum, you can make your own capacitors too. The
circuits shown in the ARRL Handbook, and the component data on winding
coils and calculating air gap plate capacitors should be all you need
to proceed to build a good antenna tuner.

2397. ICM7216 DIPI (freq.counter) chip info wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-09 00:00:00 UTC
From: kerkhoff@mail.utexas.edu
Message-ID: <3ra4s4$kra@geraldo.cc.utexas.edu>
Source record: 112553

I recently aquired a digital freq. readout at a surplus store. It has four digits
and displays freqs. from 100 Hz. to 999.9 kHz. The main part on the board
is the ICM7216 DIPI freq. counter chip. I would like to be able to modify the
circuit to indicate audio freqs. better but I don't have any info on this chip.
Does anyone know of a source of technical info and pinout of it?

Thanks for any help...

2398. Looking for an RF Ground expert?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-09 00:00:00 UTC
From: tetrault@sierra.net
Message-ID: <tetrault-0906951524300001@d221-brockway.sierra.net>
Source record: 112554

Sorry I didn't reply directly to your request for advice; you'd have the info more directly.

It's OK to have your power grounds from peripheral equipment and even RF equipment going back to the neutral bus of your house wiring. That third gounding plug on the power plug does serve a purpose, for safety's sake.

For RF sake, it is not desirable to use these connections for RF ground as the grounds have a definite and uncontrolled inductance that can make your RF equipment behave strangely at times depending on the frequency. For example, at some hypothetical frequency, you may find that the so-called ground is actually a quarter wavelength, essentially an open circuit for RF...this is not a good thing...

The classic shack in the attic is likely to suffer more than the classic basement location for obvious reasons.

What you want is, ideally, some broad strip (~12 inches) of solderable metal running along behind -all- your equipment that can accept a short direct physical connection to each piece of equipment. This broad strip is then connected to a physical earth ground as directly as possible, even using flat braid or one inch copper strip. You can buy grounding rods from a building supply for the purpose, they are copper plated steel (so you can hammer on them). If you can't solder to the connections, make them as robust as possible.

This setup, ideally, has such low impedance to earth ground that whatever impedances to ground presented by the house ground wires are shorted out, and don't matter.

You could also build a Faraday cage, but that is a house of another color...

> inductance/(turns)^2.

It has to do with the straightforward (really) nature of the physical structure that makes for a relatively simple inductance formula like nH/T^2. Take a look at a solenoidal inductance formula. The reason is the closed magnetic circuit of the toroid or also that of the core pieces like pot cores or more complicated shapes such as you might find in switchmode power supplies. They all have closed magnetic circuits that greatly simplify the process of getting the inductance for a given number of turns. Granted that the AL value is subject to typo errors, it is still much simpler than a solenoidal approach with open mag circuits.

Well, this isn't really a digital question (although it could be), or really a purely amateur question, but it is definitely a radio question, and something I know a little about. Perhaps any further followup should be conducted in rec.radio.homebrew, where the topic has appeared before, ironically in a digtal context.

The SCA "radio stations" are actually signals that are combined with the main signal of a broadcast radio station. A conventional FM radio only plays the main station, ignoring the SCA. It's kind of like the process of transmitting stereo FM, this is done in a manner that a mono radio still receives the signal properly in mono.
The "special" radios, therefore, start as conventional FM radios with the tuning fixed to the station that has the SCA signal added. But rather than play the "raw" output, they process the signal additionally to extract the SCA audio.

Uses for this technology are varied, although I don't think it ever really took off because for various reasons the signal quality is not very high, and (except in big cities), there aren't enough potential users to justify all the equipment. Also, it can degrade the main signal slightly, causing a potential loss of listeners. Public radio stations here broadcast a rather amateurish "reading" session of people reading various newspapers and magazines for the benefit of those who are blind or otherwise can't read newspapers and

magazines. In the commercial segement of the band (>92 MHz), programming is likely to be "background music" or digital services of various sorts like paging or stock quotes. In Europe, there were some experiments to link data transmitted via SCA into the "Smart Road" taxpayer-milking scheme. It is probably not legal to publicly receive these without paying a license fee to whoever is providing the service, that license fee is most likely included in the price of the special radio they sell or lease to you.

Into the more technical stuff: The SCA is transmitted as a "subcarrier" on the baseband audio. Looking at the spectrum coming out of the FM demodulator in a conventional radio, before it is de-empahsized, etc:
{Mono audio} P {Stereo Information} {SCA} (P= Stereo Pilot 19.0 KHz tone)
0 19K 38K 67K (Hz)
The SCA carrier, which is usually more than 60 KHz (57 KHz for Europe, usually 67 KHz in the USA, although it can be even higher, up to 100 KHz, especially for narrowband data), will be filtered out by a conventional radio. A good FM receiver will often include a "SCA Trap" tuned to 67 KHz to get rid of this signal entirely so it won't interfere with the stereo audio.

The SCA carrier is FM modulated with about 7 KHz deviation for an audio channel. This gives a frequency response to about 5 KHz in the baseband, so it sounds like AM radio. Actually, everything I've heard on SCA sounds *worse* than a nearby AM radio station. This is due to the other major problem: various nonlinearities in the FM transmitter, the radio channel (multipath), the IF filters, and the discriminator in the radio will cause the main channel audio and stereo information to either (1) produce harmonics in the SCA band and/or (2) cross-modulate the SCA carrier. In either case, the result is that the main channel signal bleeds over into the SCA signal, causing what sounds like static cracks and pops in the SCA when peaks are hit on the main channel, especially in stereo programming. This is not helped by the fact that the SCA signal is only about 10% of the total modulation of the radio station, so it will not take too much power away from the main channel that most receivers are listening to.

Adapters to extract the SCA signal from a conventional receiver used to be a popular magazine project, as it can theoretically be fitted to any receiver that receives commercial FM. I have built a few SCA adapters to experiment with, both magazine designs and my own, and have not been too satisfied. I also tried one commercially-produced SCA receiver and got about the same results, so I don't think my circuitry was too much at fault. I would suggest listening closely to any SCA receiver before you buy it to be sure you can live with the quality.

Message-ID: <95061004000334@tdd.snafu.de>
Source record: 112557

Hallo Roland !

Ich habe mir vor kurzem Platinen und Eprom zu dem von
Dir und Ulrich entwickelten Faxmodem bestellt.
Nach dem Zusammenbau der Platine pruefte ich zunaechst
den Daten/Adressbus mittels eines NOP-Steckers. Alle
Ausgaenge lieferten Signale, kein Signal war "doppelt".
Soweit so gut.
Nach erwartungsvollem Einbau des Eproms blieb jedoch
das Blinken der LEDs aus :-(.
PSEN- u. ALE- Leitungen liefern die richtigen Signale,
auch ein Versuch mit einem zweiten Prozessor brachte
nichts...
Ein Loetfehler ist mit Sicherheit auszuschliessen, da
ich die Platine *einige* Male daraufhin untersucht habe.
(..in den vielen Jahren meines Schaffens bin ich in der
Beziehung vorsichtig geworden ;-))

Nun gut, es laueft halt nicht, auch am Rechner kein Mucks.
Irgendwie siehts so aus als ob das Programm an einer Stelle
haengen bleibt, am Port0 steht mit Eprom immer dieselbe
Adresse an, an Port2 ist nur A10 aktiv.

Ich habe die SWL-Version 4.7 (vom Feb.94), sie ist mittler-
weile auch schon zu Ulrich unterwegs, der mir ein anderes
Eprom zuschickt.

Ich will Dir hier nichts vorjammern, sondern wollte mal
Deine Meinung dazu hoeren. Irgendwas Dummes muss ja pas-
siert sein, ich kann mir aber keinen Fehler meinerseits
vorstellen. Wenns mit dem anderen Eprom wieder nicht klappt
steht mir eine Lebenskrise ins Haus ;-)

Ach ja : ist der Software- fehler in JVFAX (FM 400 mit
ATC ==>00H) in der Version 7.0 behoben?

so, das wars dann mal

viele Gruesse

>
It is not necessary that the DC common circuit actually float. The
correct procedure is to connect DC common to the equipment ground
at only one point within any one machine. In PC type computers
there is usually done inside the power supply. In a properly
(read low noise) designed printed circuit board, the "ground" plane
is actually DC common, and should not be confused with earth ground.
In most IBM PC compatible motherboards, there is a mechanical mounting
stud near the keyboard connector that may be mistaken for a motherboard
grounding point - it is not = This mounting stud should have insulating
washers to keep it from grounding the DC common at that point. This
one item has cured many cases of mysterious behavior in PCs.

Again, the rule of thumb for grounding digital circuits is to connect
DC common to equipment ground at only one point within a machine, and
to be connect any signal cable shields to the equipment chassis at
only one end. I am aware that some terminal devices violate this
convention. My cynical response is that it helped them pass the
tests required to get it to market, but caused many service headaches
in the field, but my practical response says that there are always
exceptions to any convention - just be aware, and if you experience a
problem maybe you can identify the root cause a bit faster.

Please re-read Gary Coffman's earlier post on grounding. That is
something that could replace most of the words I have previously
read on grounding, and I checked the ARRL Handbooks section on
station grounding before placing my first post on this subject.
While it was somewhat informative, I found it woefully incomplete
in answering the all important WHY question that is so helpful
when the current conditions don't quite match the 'normal' and I
don't ever seem to encounter a totally 'normal' situation.

73,
Don W3FPR

Why is this not a good thing? Do you have some reason to want to heat earthworms with your hard won RF?

>This setup, ideally, has such low impedance to earth ground that whatever
>impedances to ground presented by the house ground wires are shorted out,
>and don't matter.

What is the impedance of Earth?

Ok, I'm poking a little fun, but think about these questions anyway. Why, in general, do you want to pump RF into the Earth? And just how low impedance is Earth anyway? If it takes a Megger to read the resistance between two points on Earth, how come our wire running to Earth has to be so low impedance? The answers to those questions can help explode some myths.

Grounded screens address the need for a good RF ground at HF. It does mean reverse biassing the cathode to get the effecteive screen voltage though the screen is at DC and RF ground. The output C of a 4CX1000A tube is doubled in Push-Pull, and probably you would not need any fixed or variable plate Tune C, just a variable inductor with variable loading C. I have seen output tanks that did this and used a compressible coil to vary turns spacing to achieve variable L.

From: blombard@iu.net
Message-ID: <D9xn31.5y3@zeno.fit.edu>
Source record: 112563

I guess the title doesn't say it all, but I'm looking for a low-cost Spice simulator that I can use for general purpose analysis. I have access to two big system Spice engines; Cadence Analog Workbench and the HP Microwave Design System. It's just very inconvenient to use them, and I'd like to have one on my desk.

Wish list: nodal input is okay, graphical output preferred. Biggest desires are (1) input spice macromodels from the various vendors' disks, (2) able to do more than a couple of dozen transistors so that I can include 2 or 3 opamps in a circuit model, and (3) DOS or 'Doze. I have the Windoze w32s extensions so that I can run 32 bit apps.

I have the freebie edition of MicroSim Pspice, but I can't get more than one opamp into it (some models are too big and I can't even get one op amp in). Likewise, I found the Papagallo Spice for Windows NT, but it allows even fewer parts than the freebie Pspice, so few that I don't even have any models I can run on it to evaluate it! The Pspice freebie version would be fine if it could just handle, say, 100 transistors instead of 10

Boy, am I fussy or what? Anyway, if there is a worthwhile version of spice out there, please let me know. This news server has a habit of missing articles, so please email, or send me a copy of your posting by mail.

73,
b

Source record: 112566

Wayne Burdick recently commented on Hambrew magazine, noting that it was $10 a year, and hinting that we should take advantage of that before they raise their price. A little historical perspective: it started out at $20 a year, which I thought was quite steep for a small quarterly publication. It wasn't a bad little magazine, but I wasn't about to shell out twenty dollars a year for it. One reason for the high cost was the publishers wanting to use very high quality paper. He recently decided to go to a lesser quality paper (but still far above newsprint in quality) and slashed the price to ten dollars a year--at which point I finally subscribed. I have no data on the effects of the price reduction vs. subscriber base, but I would suspect that he picked up a lot more subscribers when he did it. And it still remains a nice little homebrewers magazine worth looking into. 73 DE WA8MCQ

;>

These are very good points, and Paul's suggested isolation
techniques are good both in theory and practice. The only
qualification I can add is to point out that a long distance
run (like to connect terminals to computers) has a
whole lot of considerations over and above connections
within the range of the RS232 specification. The signals
used in computer to terminal operations will cause DC level
shifts due to accumulation of charge from the signal itself,
and must be dealt with in ways different from the normal
engineering practices involved in a single room or cluster of
rooms. Different signalling waveforms and protocols have been
developed to deal with just this problem. That is not
to discount anything Paul has said, but only to paint it as
a "horse of a different color".

I am looking for either a kit or plans for building a 2M CW transceiver.

Looking at all modes(new) are too expensive(and only going to get worse) and trying to find a used one is near impossible. So I have started a mission in search of.

Would appreciate any information that could be given.

Why does a 2M all mode cost as much (or more) than a low end HF rig with multiple bands?

Thanx, 73, joe

2414. Lunar 2 Meter Amp schematic and modification

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-12 00:00:00 UTC
From: au156@yfn.ysu.edu
Message-ID: <3rhivq$3f0@news.ysu.edu>
Source record: 112424

Does anyone have a schematic the following 2 meter amp that he could
make a copy of for me?

Lunar Electronics Linearized Amplifier, Model 2M10-80P.
(I guess that's 10 IN, 80 OUT, with a preamp.)

I bought this used, and haven't a stitch of printed info on it.
It's a little difficult to trace the DS PCB without separating
the two boards from the heatsink, although I have a general idea
of what is happening.

What I would like to do is to disable the SSB linear bias on the
single transistor (SD1416), because the power drain seems to be
excessive compared to a plain old Class C transistor amp. It has
an FM/SSB switch which I always thought took out the bias on these
types of PAs, but It seems to really just effect the T/R relay
lag time.

Incidentally, there is a 10 watt resistor that gets hot as a pistol
when transmitting for any length of time which must be part of the
linear bias network. For ten RF watts out, the power drain is
something like 4 amps instead of about the 2 amps I'd expect for
a plain *FM only* PA.

As a yachtie we have access to maritime bands, from where important weather information is obtained. Paging through a Maplin catalogue I came asross a CW & RTTY decoder by Waters & Stanton, a Microreader MK II. Is anyone currently operating one of these decoders or can supply information on it? I would like to decode RTTY weather broadcasts on 8 & 12 MHz (maritime frequencies). Will this decoder meet my needs? The reason why I am interrested in this decoder is simply because it does not seem to require a PC of any description to function. This is the biggest downfall of HamComm and Packet on a small yacht, as amps are scarce and salt water gets in every where!

It seems to me that I just saw an announcement that Microsim had just
come out with, or lowered the price of, a low cost version of pspice that
sounded like it would do a great deal more than one op amp.

Also, Intusoft has a windows spice package for about $500 that looks very
interesting (with virtual scope, etc). I haven't tried either package so
I can't give you and first hand experiences.

2419. 440 HT limitations and homebrewing [was: * CLOSED REPEATER QUESTION]

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-12 00:00:00 UTC
From: tvr@cnmat.CNMAT.Berkeley.EDU
Message-ID: <TVR.95Jun12113001@cnmat.CNMAT.Berkeley.EDU>
Source record: 112429
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.homebrew

This 440 band plan is in Part 97 ... guarenteed simplex ... no repeater coordinator can grab it for their friends...

These folks bought a dual band radio with two thirds of the 440 band missing. We would see similar issues raised on 2 meters if the radios were cut down to one or two MHz at the high end of that band.

That's because the manufacturers have only requested type-acceptance on 440-450 MHz. And, for my rig, there's no mod to get the rest of the 440 band without running the risk of transmitting out-of-band, e.g. it's all or nothing. I think that may have been all that was available within my price range when i got my license, so i didn't have alot of choice in the matter. Since then, a few HT cover the full band. And how is a new licensee supposed to know about these things?

During this past week-end contest there was more activity in the 432 area of the 440 band than on all two meter repeaters...SIMPLEX on 440 is between 431 and 435 if you are fm spread out from the side band guys operating slightly above 432.

Good to hear that.
Real hams know how to use a vfo and buy
multi-mode radios that cover all of the band. Some of them have been known to operate cw ... simplex no less

Real hams also homebrew, don't they? But except for 1.2G and above, almost all of the projects i've seen for VHF/UHf assume the existance of HF hardware. While there exists 440-capable IC's and off-the-shelf helical filters to solve intermod and spectral quality problems, i haven't seen any projects other than transverters and PAs (except for a simple 2 meter monitoring receiver and a discussion on how to use the R2/T2 pair [phasing direct conversion SSB] on 2 meters).

There are lots of HF QRP projects. How about ideas on how a non-HF ham can get started in homebrewing RF? (I've already build a packet modem and a 7.5V/13.8 moderate-speed charger.) Also, can folks comment on working the 'Lowfer' band?

Well, thereis the Yaesu FT290R. Not that it is a particularly
good rig, but they sell here s/h at reasonable prices.

As to building, there was in the VHF-UHF Manual from the RSGB
a direct conversion receiver. This might be a starting point.

since there is no such thing as true ground, a true RF ground expert will
be hard to find. A tuned ground system or counterpoise is useful if your
intent is in radiating energy (an antenna system), but if the efforts are in
an attempt to reduce the evils of loose RF energy, RFI and its cousins,
the material above are very good practices. W7LTQ

Well, for one thing, watt for watt, transistors that operate at VHF
cost more than those operating at HF, where gain is higher and efficiency
also.
I'm not aware of any cw-only 2 meter kits available but the ways I've
gotten on 2 Meter SSB/CW are by using inexpensive garage-sale SSB
CB radios as exciters for the VHF bands. Hamtronics sells a very
affordable transmitting converter for 144, 220, and 432 MHZ, as well
as receiving converters.
My "homebrew" 2 meter transverter consists of a Hamtronics transmit
converter (28 to 144 MHZ). Since the Hamtronics already has a good
local oscillator (LO) for transmitting, I used a 2 or 3 pf. capacitor
to tap out the LO (116 MHZ) energy from the TX converter to the mixer
(40673) of a homebrew receive converter a la the older ARRL handbooks,
my favorite lowcost high performance converter being the "Rochester"
converters. I used spdt reed relays with rg58 shield surrounding them
and wound with a homebrew coil for coaxial relays for this transverter,
though Motorola replacement relays for Micor and Mocom 70 radios cost
around $20 apiece last time I bought any and will work fine too.
This design is a bit dated with most using Mini-Circuits mixers instead
of 40673's or modern day replacements but it still works fine and has
a total cost of less than $100.00.
6 meters can be accessed a number of similar and other ways. I
converted an old garage sale SSB CB directly to 6 meters by installing
a different LO crystal in the "crystalplexer" to produce desired 50
MHZ operation. Had to remove all the padding caps in the RF stages
to get it to tune properly that high in frequency and when I got done
the TX power was close to stock (5 watts) but the RX needed a preamp
to get it to hear decently. Plus, I only changed one crystal which
resulted in only 4 channels at 50 MHZ but those 4 were 50.100, 50.110,
50.120, and 50.140, which gave me years of good activity when I was

still active on 6.
Many have done the same thing, changing the LO crystal, to the Heathkit style HF transceivers (HW-100, HW-101, SB100, SB102, etc) which gives them 6 meters on an old tube-type transceiver! The ones I've talked to just changed out one of the crystals for a less desired band. The tuning is done normally, albeit a bit sharp on 6 meters, little to no other mod required.
Lots of ways to skin a low-cost cat......
Jim WB5AOX

2424. Re: NEED HELP! Respond : Grounding 'Experts' !

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-12 00:00:00 UTC
From: k23690@proffa.cc.tut.fi

Source record: 112567
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.digital.misc

This is drifting a bit off the original topic, but here is some thoughts of how to operate computers, computers and TNCs or computers or remote rotator control boxes in different rooms or different buildings and how to solve the ground potential/ground loop problems.

This is based on my experience planning and maintaining computer terminal networks that are spread over a large area (one or more buildings). It is also based on the 4 wire wiring practice (three phases and neutral) used over here (230/400V) and thus is not directly aplicable to the U.S. wiring practices, but the principles are the same.

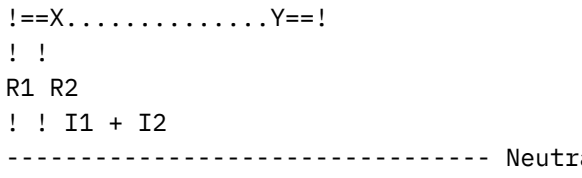
In a three phase power distribution system, no curent is supposed to flow in the neutral wire if all phases are equally loaded. The neutral wire is connected to the earth at the power company and usually in every house. In homes and offices most loads are single phase (connected between one phase and neutral) and thus the full load current is flowing in both the live and neutral wire in the cable between the fuse box and the load (wall outlet, lamps etc.) The neutrals from these cables are connected together and some cancelling takes places if loads are powered by different phases.

The protective earth (PE) in a 3 terminal wall outlet is connected to neutral in any convinient place, previously this was directly in the wall outlet, but nowadays this is usually done in a distribution box feedig the outlet.

In the ASCII drawing below, two loads are connected to the same phase (this is the worst case, but full cancellation will not occure even if they are connected to two different phases) and some computer equipment is connected to the same outlets as these big loads.

Current I1 is returning from load 1 flowing thrugh a lead resistance R1. In a similar way the return current I2 from load 2 flows through lead resistance R2. Two equipment X and Y (say a PC and a TNC) are connected as shown, the == symbol indicates Neutral and PE (the live connection is not shown). The PE is connected to N at the wall outlet or some other distribution box close to it.

```
Live I1 + I2
-------------------------------------
! !
Load1 Load2
! !
I1 ! ! I2
! Rs !
```



Putting in some typical values to illustrate what happens.
If R1 = 0.3 ohms and R2 = 0.3 ohms and I1 = 1 A and I2 = 10 A,
then X is at 0.3 V and Y at 3 V and a 2.7 V potential difference
between X and Y. If the DC-ground is connected to the chassis in
both equipment, then this voltage difference can be measured between
the signal ground terminals (pin 7). If a serial cable is connected
between the equipment with signal ground lead resistance Rs of 2.7 ohm,
allmost 1 A is flowing through the signal ground lead and also through
the circuit boards of both equipment.

The noise margin is greatly deteriorating, since the transmitter
generates the output voltage relative to its local ground reference
and the receiver senses the input voltage relative to the local ground
at its end of the line.

If a thicker wire is used, the current between X and Y will increase
and the voltage difference will drop improving the noise margin.
If Rs could be set to 0 ohms, the voltage difference would dissapear
but 4.5 A would flow through the traces on the PCB causing lots of
problems.

However, if the protective ground (pin 1) or a separate pig tail is
connected directly to the chassis _at_both_ends_ and a better conductor
(such as the shield of the cable) are used for protective ground, the
current flow through the PCB is reduced to a tolerable level.

IMHO, this is far from a good situation, since large currents are
flowing in the shield with a potential fire risk and the current will
induce interference currents into the signal lead. Connecting and
disconnecting the serial cable will most likely burn the receivers or
transmitters if done in the wrong order.

There are several ways to improve the situation

a) Rebuild the power distribution system in the building so that the
PE is kept separate from the neutral and the PEs from the wall outlets
are brought to a single point. This point is also connecting to the
neutral and the grounding electrode of the building. In the normal
(no isolation fault) case, no current is flowing in the PE network
and consequently there are no voltage drops in the wiring, thus all
PE terminals in every wall outlet (and all chassises) are at the
same potential and no ground loop currents are flowing in the serial
cable, even if the the signal/protecting grounds are connected.
This 5 wire wiring system (3 phases, Neutral and PE) are installed
on all new office buildings. However, this solution is usually not
practical for old building, neither does it help if you are connecting

two computers in two different buildings with each own grounding
electrode.

b) If the DC ground of one of the equipment can safely be floated, such
as an external modem powered by a double isolated wallwart, this is the
simplest solution. The cable shield should only be connected at the
grounded equipment end.

c) Use balanced (such as RS-422) lines. In this case both equipment can
be grounded and no signal/protective ground lines are connected in the
serial cable. As long as the ground potential difference between X
and Y are smaller than the common mode voltage range of the receiver
(usually 6.. 30 V) this will work fine. This is currently often used in
industrial sites, where there can be quite large ground potential
differences.

d) Use completely isolated (no galvanic connection) connection between
X and Y. The simplest way is to use current loop (20 mA) signaling
and optoisolators. The cable shield should be connected at one end only.
This was previously (at relatively low data rates) the most common way
to get around the ground potential problem. My suggestion (in a previous
post) to use audio transformer between the TNC and the rig is a variation
of this principle.

Now, responding to Don W3FPR

========================

Yes, this is good engineering practice, but look what happens when we look
at the situation at network level. If we have one computer and some
floating device at the other end, then we can apply principle b) above.
However, if you are trying to connect two computers, then principle b)
can no longer be applied due to the grounding in _each_ PC. This was
just the situation with a cumputer and multiple VT100/VT220 terminals,
which are connected just like PCs you described. It does not matter what
you do with pin 1 (protective ground), you will have circulating ground
currents through pin 7 anyway. In this case it might be better to connect
both ends of the cable shields for improved noise margin, but I do not
recommend it after having replaced line receivers on several terminals :-)
You should newer break the signal ground (pin 7) connection on RS-232 to

break the ground current, since you will end up with burnt receivers and transmitters very quickly during normal operation.

My recommendation is to ground equipment properly for electric safety and use isolation (optoisolators, transformers etc.) to transfer the signals.

Sorry for this long ranting, but hope that someone might find something useful, next time when someone is connecting together equipment in different rooms or different buildings.

FLEA all SUMMER at MIT
June 18th, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

>multiple ground rods together? Something like this
>
> Ground Rod --------+ +--------Stuff in shack
> | |
> Ground Rod ---------+----------+--------Entrance Panel
> | |
> Ground Rod ---------+ +--------Tower, etc

Daisy chaining of any sort is generally to be avoided. However,
this is not a daisy chain if I read the diagram correctly. What
you have is a star connected group of grounds (I'm assuming you
left out a couple of |'s in the drawing) that are connected to
a single entrance point. That's a perfectly acceptable way to
do it. IE

```
G
|
G---x------------------->house
|
G
```

That's fine. Now, if you were to do this;

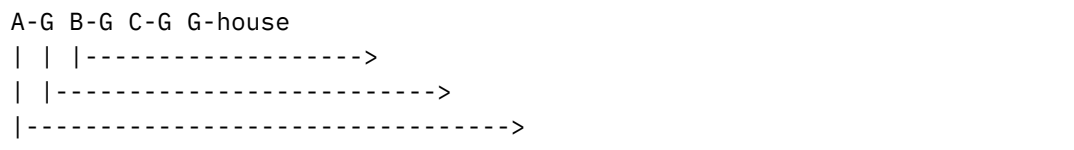
```
G------G------G-----G------G--------->house
```

That would be Ok too, but not as desirable because of the accumulated
voltage drops in the daisy chain. What you want to avoid is this;

```
A----G----G----B-----G-----C----G->house
| | |--------->
| |---------------------->
|----------------------------------->
```

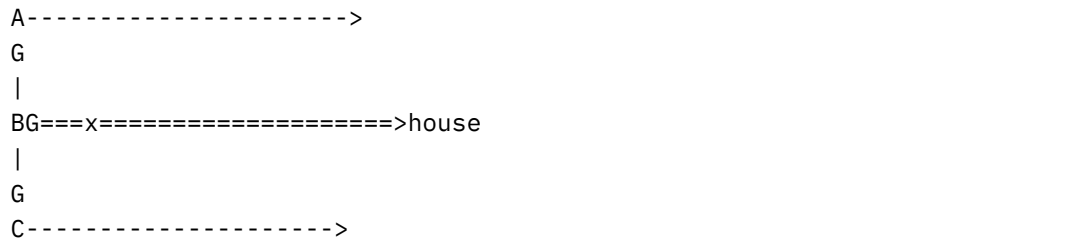
with A, B, and C representing antennas or other external
equipment. Now you have a nasty ground loop through the
chain of G's and that's going to lead to trouble. If you

do this;



This is *real* trouble. Now you're depending on the (poor) conductivity of Earth to tie the grounds together, and they'll be at wildly different potentials during a strike. Those potentials will be reflected on the cables from A, B, and C, and will do big time damage to the station if not shorted by a ground window.

Now the better way is to do this;



B's cable closely parallels the star ground run in the drawing. Since A, B, and C's grounds are tied in star, they will be at nearly the same potential. Best, however, would be individual ground runs from A, B, and C's grounds back to a single common point at the house. That avoids any ground loops.

Any of the situations that create external ground loops can be shorted by a ground window at the station entrance. That will protect the equipment *inside*, but equipment in the external circuit, preamps, rotators, etc, can still be damaged by the circulating ground currents. So it's best to avoid ground loops in the external circuit and always use a star topology.

Remember, for lightning, just having good DC conductivity isn't enough. In the first place, at 8,000+ amps of surge, even good conductivity is rarely enough to prevent substantial voltage drops. More important, however, is that lightning is RF, and low *impedances*, including reactance, are important to keep the potential differences at bay. It's always the *difference* in potential that matters. It doesn't matter if everything becomes elevated in potential, as long as everything is elevated to the *same* potential. Star topology is important to make this happen.

Gary

In the interest of home (and ham) safety, let me tell you about my experience earlier tonight.

Funny what happens when you are talking about grounding. During a storm yesterday, one of the GFI circuits in the house was tripped. Problem was that it wouldn't reset, so I went hunting for the cause. I found a defective outlet, but along the way I also found some other things that made me shudder - in the first receptacle along the wiring path, I found an exposed neutral wire that broke when I examined it. Having repaired that, I was hoping I was done, but no such luck, the next outlet on the string had 2 outbound wires from the outlet box, and there was *no* safety ground wire connecting to the duplex receptacle and the safety return wires were not adequately connected together. Correcting the open ground wire condition finally lead me to the culprit receptacle on the rear deck.

What is my point? Simply stated - trust nothing until you have checked it out. This is in a recently built house in a community that *supposedly* has one of the toughest inspection teams in the area for new structures. You can be certain that I have a task ahead of me, and I will not rest comfortably until I have checked each and every connection point in the electrical system here.

I will also be communicating what I found to the town council and the building inspection department. This is the least I can do for the protection of others as well as myself.

73,
Don W3FPR

Gary Coffman (gary@ke4zv.atl.ga.us) wrote:

: A ground window is simple in concept, and simple in execution.
: Basically, it is a physically small conductive plate through
: which *every* cable that enters or leaves your station must
: pass. Every cable that is supposed to be at "ground" potential
: is bonded directly to this plate as it passes through. Every
: conductor that is not supposed to be at "ground" potential
: is bonded to the plate via an appropriate suppressor device.
: (A book could be written on that subject alone.) Then the
: plate is connected to your single point ground by a heavy
: low inductance strap conductor. Now any large potential
: difference that tries to express itself across cables
: connected to various cabinets in your shack will find itself
: shorted out at the ground window.

Question: Does every cable have to pass _through_ this, or
could this ground window be, for example, a strip of aluminum
along the back of the table (protected from accidental touching,
of course) to which all grounds for all pieces of equipment are
connected? All the power connections, serial cables, etc. such
as you mention would have their ground connection applied to
this aluminum strip, and that would be connected to the house
grounding system, probably via an outlet box as there are no
pipes in that area to connect to.

Workable?

Kanga US sells the KK7B single signal direct converstion stuff as either just
boards or complete kits. You *could* make a 2 metre CW/SSB transceiver
with those. I've been thinking about building one up myself.

I think Kanga's URL is http://ncc1701-d.cc.nd.edu/kanga/.

Looking for the following relay:

Potter & Brumfield R10-E1Y4-J10.0K

This is 4PDt current-actuated relay with
a 10,000 ohm coil. Also need socket.

This relay will replace a P&B MH-3665-1
relay with similar characteristics,
manufactured for Hallicrafters in 1958
for use as a changeover relay in the
HT-32A.

Obviously, a MH-3665-1 would be just
fine too!

Socket also need if appropriate.

Thanks!

While I am not much of a processor expert either, if you just need something to start with that will verify the operation of your PLL designs, Motorola National and Philips all offer test programs for their respective synthesizers. These programs run on a PC and send the PLL programming data, clock and latch signals out 3 wires of the parallel port. You can connect these lines directly to the PLL.

I have worked on the analog/RF side of satellite receivers which use the 8031 and its relatives as a controller for multiple synthesizers.

Good luck

Steve Muther WF6R stevem@w6yx.stanford.edu

moritz@ipers1.e-technik.uni-stuttgart.de wrote:

: I saw the design in the wireless world. It looks very much like an
: aprils fools joke,

It does, doesn't it. Believe me, the people who originated it take
it very seriously indeed and spent a lot of time and money on patenting
it. Whether it works effectively is a separate question.

The idea of simultaneously generating E and H fields is perfectly
valid. Conventional antennae generate one component field predominantly
and the other develops as the field propagates through space. An antenna
that really did create both would simply have no "near field" region
with unbalanced E and H components.

So far so good. There is nothing that makes this *implicitly*
inefficient, or troublesome. Where I have doubts are:

Does this have any influence on antenna size versus frequency?
Does it permit directional concentration from small structures?
Are the field generators efficient ?

From having seen demos and having had a close look at them, my chief
concern is with the effectiveness of the interface between a 50 Ohm coax
environment and capacitive structures. I suspect that this area could
easily spoil the performance of the whole thing, and it would be easy
but erroneous to interpret this as invalidating the basic principle.
Synopsis: the basic principle is novel, interesting and deserves
thorough investigation, but I feel the implementation of the things so
far seen in print leaves room for much further development.

:I am surprized that the G-QRP mag bothers with it.

George is open to publishing just about anything in Sprat, there is
no heavy technical vetting, though he does sometimes mail stuff to
various people with "What do you think about this..." notes attached
While this openness means that readers have to be selective, it
provides a channel for occasional odd ideas and unusual approaches that
can stimulate new ideas

I didn't take the tin can CFA seriously when I saw it in Sprat, I
found it amusing, but guessed that you could likely get comparable
results by tuning up to a wire coat hanger.

: Try a wet shoe lace first.

Probably not far off some of the oddball antennae ;-)

Cheers

I followed the whole thing over about a year. As I recall no one could
duplicate the results. WW would print some stuff that was a one time
non repeatable event.

Some where I have a copy of one of their articals that observed signals
traveling at greater than the speed of light. I talked with an EE of
considerable reputation that thought that it was possible that two
converging signals could produce a phase front that exceeded the speed
of light.

PHASE VELOCITY <> GROUP VELOCITY!

In waveguide, phase velocity is always greater than the speed of light
in the medium in the waveguide (usually air), and approaches infinity
at the cutoff frequency. This has nothing to do with violating the
law of relativity.

Imaging a wave in the ocean moving at 10 MPH hitting a straight
beach at almost perpendicular incidence. The wavefront will "move"
along the beach at hundreds of MPH. But the wavefront is a mathematical
abstraction, not a physical object, so the swimmers are in no danger
of being swept away in a tidal wave.

I've heard about a range of frequencies allocated for personal use (cordless phones, remote controls, etc.) within one's own house on limited power. I wanted to know if there was a way to build my own equipment on such bands.

Interesting possibilities might include homebrew cordless phones, possible ways to put your xmitter closer to the antenna by having a remote control full-duplex repeater in your hand where you like to work.

Post some stuff up if you have any ideas. Thanks.

Hi Clark... I have sucessfully used an Intel 8031 micro to control
a Motorola MC145190 serially programmed PLL chip.
Also used and 8031 to control the Kenwood TM-741/742 series of VHF/UHF
modules independant of the radio (same idea...serial programmed).
You basically need 3 parallel I/O lines...CLOCK,DATA and ENABLE.
Toggle the ENABLE line then clock the data in, i bit at a time.
The basic concept is not difficult but the trickier programming comes
into play when you want the thing to be frequency agile as well as
control a display and deal with input from a keypad or rotary encoder.
Let me know if you have any specific questions...
regards...Hugh Duff VA3TO Toronto

Does anyone have any experience with remoting an transmatch? If you have, I would very much appreciate your sharing what kinds of motors, indicators, etc. you usd.

I have seen a number of likely candidates for motors in the Herbach & Rademan and Fair Radio catalogues (other sources?), but I'm undecided about the number of rpm's to have to drive the varible capacitors, rotary inductors, and maybe switches. (Remoting switches seems to be another can of worms all by themselves.) One person suggested using electric screwdrivers, but they seem less practical that reversable moters.

Anyway, a hamfest a couple of weeks ago yielded several key components I had been looking for and I'm getting dangerously close to actually starting construction. Any advice will be most appreciated.

Simon,

If the fact, that an antenna design is marketed had to do
with it's quality, we would have to re-write engineering textbooks
and possibly even Maxwell's equations.

Well, on amateur radio conventions you see really fancy dummy loads.

BTW, Do you have their adress? if it sells well, I will be happy to
market them over here.

Yes, the idea is the entrance panel is connected to several ground rods using individual cables and then not only regular house wiring but also the tower and shack rf wiring goes to the same point. Like a big star. (For some reason I can't draw that)

Where my scheme breaks down at the moment is that the tower has two individual ground rods and there is one on each of three guy wires. I'd guess that could cause a loop, eh?

Thanks,

Larry

Connect them in a star at the tower base, and then connect that
point back to the star at the house. A star of stars is an acceptable
topology.

Current practice (i.e., what I've seen recently) on mountaintop radio sites around here seems to be to have replaced the feedthrough ground plate with a simple grounding bar to which all of the incoming coaxes are bonded before they enter the building.

I can see that this is simpler and much less prone to water entrance problems, and it seems to me this might be adequate.

Is this the new practice or did someone just get real lazy?

2462. High Efficiency MOSFET HF Transmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-14 00:00:00 UTC
From: cloutier@eisner.decus.org
Message-ID: <1995Jun14.125209.10242@eisner>
Source record: 112466

First, hello and all. This is my first time in this news group.

I'm curious if there are any fellow readers out there who are interested in building high efficiency solid state or low impedance tube transmitters for HF?

If anyone has built such a transmitter, I'd like to know your experiences.

I have just recently completed a 180 Watt (input) solid state transmitter for 75 and 160 meters. It uses the cheap IRF610 power mosfet (cost of between .75 and $1.00 each). The transmitter uses 18 such fets in a totum pole arrangement.

The efficiency is achieved by running the MOSFETs as switches and keeping the rise and fall times very low (10ns typical).

Currently, this is set up for AM, and I'm modulating the final with 6 IRF620 Mosfets set up as a Pulse Width Modulator. If you're not familiar with a Pulse Width Modulator, it's simply a highly efficient series modulator. It's standard AM at the output.

I'm getting around 90% efficiency. I'm using standard TTL throughout, with some Mosfet drivers (from motorola, .60 each) to achieve the higher voltage (10 V) needed to drive the gates of the MOSFETS.

The transmitter is very simple. So is the modulator. The transmitter uses no oddball ferrite transformers and the output network is a standard L-PI network built with broadcast variable capacitors and air core coils.

While this transmitter is interesting and all, I don't think I could get the thing up above 75 meters using this design (switching at RF to get high efficiency). MOSFETs have a fairly high input capacitance, and a high reverse transfer capacitance which increases dramatically when the Fet is in saturation mode.

It is quite practical to drive these Fets as a linear amplifier, but that would be highly inefficient.

I'v been thinking about building a similar transmitter using the 6C33C-B triode. This tube is a very low impedance device (around 100 ohms), and should easily do 300 volts at 600mA per tube. Given that, it would be farily easy to build a KW transmitter with 5 or 6 of these tubes.

I'd run 300 volts at 3.3 amps or thereabouts. It could be easily modulated by power mosfets set up in a Pulse Width Modulator.

I suspect it will take around 100 volts (RF) to drive it into saturation. I'd probably use a couple Mosfets in totum pole to drive the grid with

square waves. I'v achieved 90% plate efficiency tubes in the past, buy using square wave drive, and turning the tube on hard.

Anyone had any experience with the 6C33C-B, or for that matter with using MOSFETs as RF switches.

One parameter I can't seem to find for the 6C33C-B is the maximum grid dissipation.

Regards,
Steve KA1SI (Northern Mass).

Try Future/Active Industrial. They have an amazing stock, and their prices
are lower. You will not be able to buy onzie-twozie quantities.. for
ICs, you'll probably have to get a minimum of 10, but you'll also find that
for some items they are 80% less (yes, a $4 item at digikey costs $1.70
at FAI - I bought such an item) in cost.

tel: 508-779-3111.

THere is probably a division near you.

DIsclaimer: I don't work for FAI or have any association with them except
for being a satisfied customer.

Regards,
Steve Cloutier, KA1SI Mass

Motorola in the same source depicts the low noise circuit, which is a narrow band amp. Recent articles in QST (last three years, by Mahkinson and Ulrich Rhodes, et al) describe broadband 50 Ohm I/O low noise amps with high intercepts (approx 45 dBm) that are bipolar and have not the high current consumption of the Motorola FET.

Archive-name: radio/personal-intro
Revision: 2.1 1994/11/01 03:50:23
Posting-Frequency: posted on the 15th of each month

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet mailing list counterparts and complements. It is intended to serve as a guide for the new reader on what to find where. Questions and comments may be directed to the author, Jay Maynard, K5ZC, by Internet electronic mail at jmaynard@admin5.hsc.uth.tmc.edu. This message was last changed on 31 October 1994 to add the discussion of non-Usenet mailing lists and streamline most of the history discussion, and to change the moderator information for rec.radio.info.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions were held on the mailing list, and sent to the mailboxes of those who had signed up for it. When the Usenet software was created, and net news as we now know it was developed, a newsgroup was created for hams: net.ham-radio. The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became progressively higher. First one by one, and then as part of two reorganizations, what was once one group became many. In the process, developments elsewhere on the net were reflected in the groups as they were created, most notably the change to place all of the ham radio groups in one hierarchy.

The collection of newsgroups continues to grow as more people join the net, and as more topics of discussion gain volume, I expect to see more groups be created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the notable exception being rec.radio.swap. There are also a few mailing lists that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them, and not to the groups that aren't. The whole idea of having different

newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

All of the following mailing lists are sponsored to the Boston Amateur Radio Club, as well as some others of local interest. Thanks to N1IST for the information.

qrp-l: This is the qrp mailing list, previously maintained by Bruce Walker at Think.com. It is for discussions about the design, construction, and use of qrp (low power) radios and related equipment.
arrl-ve-list: This is a one-way list, run by Bart Jahnke of the ARRL VEC, for announcements to VEs and VE teams.
w1aw-list: ARRL bulletins, news, and information
newsline-list: Redistribution of Amateur Radio Newsline
letter-list: Redistribution of the ARRL Letter
fox-list: Fox hunting and Radio Direction Finding
fieldorg-l: ARRL field organization discussions
ham-tech: Technical discussions and questions about Amateur Radio
arrl-exam-list: amateur radio license examinations scheduled in the US and in some foreign areas.

To sign up or inquire about these lists, send mail to listserv@netcom.com with the following in the body (subject is ignored) of the message.
<listname> is the name of the list to subscribe to.
To subscribe: subscribe <listname>
To unsubscribe: unsubscribe <listname>
For more information: help
To post (to the two-way lists), send your message to <listname>@netcom.com

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while

still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

2469. Re: NEED HELP! Respond : Grounding 'Experts' !

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-15 00:00:00 UTC
From: tvr@cnmat.CNMAT.Berkeley.EDU
Message-ID: <TVR.95Jun14220209@cnmat.CNMAT.Berkeley.EDU>
Source record: 112376
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.digital.misc

I found a defective outlet, but along the way I also found some other things that made me shudder - in the first receptacle along the wiring path, I found an exposed neutral wire that broke when I examined it. Having repaired that, I was hoping I was done, but no such luck, the next outlet on the string had 2 outbound wires from the outlet box, and there was *no* safety ground wire connecting to the duplex receptacle and the safety return wires were not adequately connected together. Correcting the open ground wire condition finally lead me to the culprit receptacle on the rear deck.

What is my point? Simply stated - trust nothing until you have checked it out. ...

Right! Folks, (if you haven't done so already) get yourself what some of us in the computer business refer to as a "Win-Lose" box. You plug it into an outlet, and two out of three lights will light up at the same intensity if things seem to be wired right. It's not perfect (my own apartment fails in an odd way, which i recognized by slightly dim light, which i know is hard to fix, being old enough to be pre-conduit), but at least you will know what you're up against. Likewise, if you're moving into a new building, do yourself a service and go around checking every outlet so you find out while it's still easy to fix.

>Now, doing this in a lot less bandwidth than RTTY and error correction,
>under worse conditions than CW?? That deserves some explanation!

We are limited to 300 baud on our HF bands below 10 meters by 97.305,
and on 10 meters we are limited to 1200 baud. However, note well that
baud is a technical signaling term, and baud does not have to equal
bits per second.

Yes, and that's one reason that the 1200 *baud* limitation does not seem
so bad to me. Let's take that up to the 440 band. The motorola single-IC
UHF transmitter does both AM and FM, and can do both at once. So, i guess
there's two bits per transition right there. More seem possible with an
DAC/ADC, and indeed folks like Maxim already make such chips. So, instead
of running 9600 bps, it doesn't seem hard to go to 19.2 without increasing
the channel bandwidth. Right? And bandwidth is the major concern; the
intent is not to force us to go slow.

It's common to overload a single baud with multiple
bits. All modern telco modems do it.

As us computer people have been aware of for years. For example, having
four phase states per transition, which is how the old 1200 bps Bell modems
did it. And before they became prevalent, some of us ran 1200/150 modems
(many homebrewed), as we can't type that fast anyway! That's right, folks,
the same thing we run today on VHF, but with an almost subaudible reverse-
channel.

There's a nice chart in reasonably current ARRL handbooks that summarize
Bell and CCITT modem characteristics [p. 19-34 in the 1993 edition].

I'm not speaking about use of
such techniques above, however, since they aren't necessary to get
the performance I quoted. The signaling technique I was alluding to
was simple MSK. Adding FEC etc would reduce the effective data rate
from the raw numbers quoted. Sorry if I didn't separate those two
ideas clearly.

Let's see now, it says MSK is minimum shift keying, "a form of FSK in which the frequency shift is one half the signaling rate in bauds" [ibid., p 19-30], i can't seem to find out much more about it than that. I guess FEC [ibid., p. 21-6] is like what us computer-folk know of as ECC, a fairly powerful technique...

The 60WPM figure is for a raw Baudot alphabet without error correction at 45 baud using MSK modulation. The 1.4 Hz/baud figure would apply to any alphabet of course. For example, we are limited to an occupied bandwidth of 1 kHz on the lower HF bands for data transmissions. Using MSK, we could run up to 714 baud in that bandwidth if baud higher than 300 were permissible. Using symbol overloading so that one baud represented more than one bit would increase our effective bps even further, of course. Examples of that sort of thing are QPSK and QAM. Those techniques aren't as parsimonious of spectrum as MSK though when SNR is included in the equation, IE we'd have to run higher power to get the same BER and thus limit frequency reuse to an extent.

OK, so QAM is how Bell/CCITT would run 9600 over their voice-grade lines, but i'm not sure what QPSK is like. What escapes me is how any of this is relevant to a homebrewer...

Now 97.309(a) limits the alphabets we can transmit on HF to Baudot, ASCII, and ISO646. So we can't use unspecified alphabets on HF. But that does not limit how we generate modulations to transfer those alphabets, IE how we express those patterns of ones and zeros as RF, nor does it prohibit us from using higher level protocols to facilitate the transmission of those alphabets, IE block codes, FEC, etc. Nor does it limit us in what those alphabets may *spell*. For example, we can transmit binary files by UUencoding them into the ASCII alphabet. Being restricted to only 3 alphabets is a burden, but not a serious one. We've had to deal with such limitations on computer networks for years. An 8 bit alphabet would be more natural, but we can live with the limitations of a 7 bit alphabet, albeit with considerable unnecessary overhead.

Thank you for explaining that, it wasn't clear to me. So we don't have to use straight ASCII or straight Baudot, there merely needs to be some kind of mapping into one of those whose intention is facilitate communications, not obscure them.

>I studied carefully the R2/T2 pair, and have thought about doing such
>for 10m and above (noting that some of the RS birds go in on 2m and out
>on 10m) Does that mean it's simple enough to be a QST project, albeit
>probably not as easy as a QRP rig?

Sure. I've seen a number of projects in QST that were far more complex than the GRAPES RF modem (whose baseband is at 10 meters). Note that

the GRAPES modem implements MSK, but it isn't the only way to implement MSK, and other circuits could do so with fewer parts, and/or higher performance for HF usage. It is, after all, intended for high speed usage on the UHF spectrum via a transverter, but it does implement the necessary bandwidth conservation techniques, so it serves as an existance proof for the technique.

I didn't realize GRAPES does MSK. It makes sense, though. Is there any on-line documentation of that device?

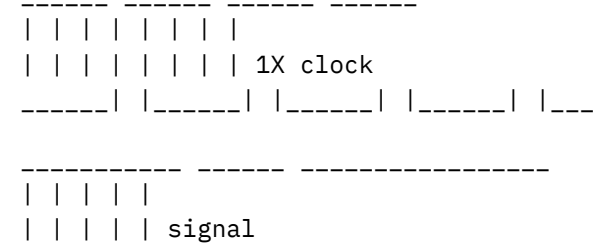
...

filter and time constants in the Costas loop. Use of simple DSP would probably make the whole exercise trivial for the baud available at HF. At the time the GRAPES modem was designed, suitable inexpensive DSP chips weren't available to deal with 56 kb and so the design had to be implemented in hardware. That adds circuit complexity that could be eliminated by use of any one of several currently available DSP chips. The GRAPES design is 8 years old, and was intended to be simple, cheap, and easy to build with parts commonly available at the time.

Yeah, using a DSP to be more than brick-wall filter for CW makes alot of sense in the HF world. I bet it could do neat things to SSB as well. I'd like it if someone would come up with DSP circuitry to run moderate (>19.2Kbps) speed packet. Heck, if someone were to properly explain the algorithms, and provide a PROM burning and/or download facility, i might even be convinced to look seriously at doing the programming.

However, the Lowfers have been using low rate codings implemented in hardware for a number of years with remarkable results. They're using effective bandwidths on the order of 0.01 Hz with nothing more elaborate than some opamps, tri-state analog switches, and TTL logic.

Wow! How does one get started in the Lowfer band (especially if one has no foreseeable interest in HF equipment)? Again, is there on-line material on this? I've never gotten along very well with the local Postal Service...
The key to
effective operation is clock synchronization. Once you have that, correlated oversampling will quickly tighten the effective passband and rapidly raise the effective SNR. Perhaps a word about this would be useful. Assume data synchronized to some clock using a simple coding scheme (a Manchester code in this case).



```
______| |_____________| |______|

0 0 1 0 data
```

A transition of the signal on the falling edge of clock signifies
a 1, no transition on the falling edge of clock signifies a 0.
It doesn't matter which way the signal transitions, only the change
of state matters. The signal always transitions on the rising edge
of clock, thus embedding clock into the signal.

Right, MFM (called DM in the Handbook [ibid., p. 19-38, also Figure 41])
allow one to recover both the data and the clock, and run at a baud
rate less than or equal to the data rate.

Now if we recover this signal and sample it with a 1X clock, we'll
be looking for the transition on the falling clock edge to determine
if we have a 1 or 0. To resolve that we have to have a fairly high
bandwidth, something on the order of 3X to 5X the clock rate or greater,
otherwise the edges of the signal will be smeared and rounded by the
IF filter and prevent a clear decision. This is undesirable since
it limits the achievable SNR. Adaptive slicers can help a little,
especially for signals that are slewed, but not much.

However, suppose we sample with a high multiple of the clock rate,
say 16x, then we have 8 samples before the suspected transition
and 8 after. If we accumulate these samples and compare their
sums at the end of the bit period, we'll have effectively narrowed
our bandwidth to 1/8th it's previous value with respect to short
duration noise, and we can now use a narrower analog filter with a
bandwidth on the order of 2X clock since a sharp edge is no longer
required to pass in order for the 1 or 0 decision to be made cleanly.

Yeah, they used to make IC's to do just that about a decade ago, like
the old 6409. Alas, nowadays, such logic is buried deep inside a disk
controller chip, or if not, expects to run in the megabit region (+/-
an order of magnitude or so). Maybe i haven't looked hard enough.
Yeah, it needed something like x16 or x32 clocks. (But UARTS want that,
too.)

With an even higher oversampling clock, we increase our effective
SNR even more. Now this assumes that the sample time is on the order
of, or less than, the average noise hit. To assure that, we may
have to lower our data rate so that the symbols are long with respect
to noise pulses. But we don't have to narrow the analog filters in
our radio by the same amount to gain the SNR advantage. The sample
and accumulate process has the effect of narrowing the bandwidth
with respect to noise.

Of course, we don't need analog filters at all with a DSP, and then one
can use filters that don't do annoying things, like ring.

Now the GRAPES MSK modem doesn't use this technique, but the Lowfer
system does. It's a fairly powerful technique for low rate signals

that's easy to implement in hardware (it's basically the principle
of a switched capacitor filter, but with the added feature of having
the sample clock locked coherently with the desired signal, and that's
a major improvement). Now, we can extend this same method, or better ones,
there are much better ones, to individual RF cycles if we have sufficient
hardware speed to deal with the high sample clock.

Or i presume if we want to operate in the VHF region, we can play these
same games, and use a DBM to get in and out of the desired band.

Now we have a powerful
technique indeed for separating coherent signals from incoherent noise. The coherent
samples add constructively, but the random noise does not, IE a
rising edge always increments over a series of samples, but the amplitude
of incoherent noise may go down as likely as it goes up at any sample
because of it's statistical nature. Thus it tends to sum to zero, or a
constant bias, over a large number of samples. Foreknowledge of the
phase of the desired signal is one of the most powerful techniques for
separating desired coherent signals from a chaotic channel. It's the
basis for the astounding weak signal performance of the NASA DSN.

OK, but can i do it at home?

>There must be some problem here i don't get, such as it's in a mode
>that we can't use yet in HF... But wait, i might still be able to have
>fun with such a device at 6m and above, where we can try out new coding
>schemes. Please, tell more, and if you want to UUENCODE diagrams and/or
>schematics in some well-known format, i'll even put it in my WWW page for
>others to access.

Clover is an existance proof that modulations other than simple FSK
are allowed on HF. It's perhaps more complex than necessary because
it has to work through ordinary analog SSB radios which are very far
from optimized for digital transmission, but the fact that it exists,
and is permissible under the rules, is ample proof that we can use
other modulations for digital data at HF than crude FSK.

Good, so there's something to point at when someone looks at me askew after
hearing one of these new signaling methods.

By and large, amateurs haven't used more advanced digital modulation
techniques on HF because (a) they don't know about them, (b) they
think they are too complex or difficult to understand, (c) they
believe (falsely) that they are illegal, (d) they're so brainwashed
into the manual Morse and analog voice paradigms of communications
that they reject out of hand better digital methods, and (e) there
have been no commercial Japanese products implementing the techniques
for amateurs to purchase.

I don't know what we can do about (d), and i'm not sure what folks who
fall into category (e) are doing in the amateur service... But (a), (b),
and (c) are things that are changable. An good article in QST might at
least dispense with (c) and possibly make a dent in (a) and (b). It's

too bad than coded technicians can still only operate non-CW on 10 meters.
No wonder the real work is happening in the 'Lowfer' band.

As for the GRAPES RF modem, its details were explained throughly
by Dale Heatherington (its designer) in one of the ARRL Computer
Network Conference Proceedings. Look for a paper on the WA4DSY
modem if you want to know more. Again I would note that this serves
merely as an existance proof for the technique. Alternate implementations
optimized for low rate signals would serve better for HF operations.

There's alot on the WWW about such things, i'll have to see if that's
on-line or merely referenced. I know the GRAPES folks have some WWW
stuff, so i'll report back if i find it. Please tell more about MSK,
and while the signal schetch was appreciated, again, circuits would be
nice, particularly things we could try out on our own, even just 'on
the bench' [literally or computationally].

I am in the air conditioning trade where this comes up more often and it a real pain
to deal with. There are low temp solders, the flux is acid-based, electrical connections
shouldn't be made with acid-based flux, but thats not all...
Aluminum needs to be extremely clean. Sandpaper is needed. The oxide layer is
very tough. This oxide rapidly reforms and will ruin any soldering job. I have never
tried a soldering iron as a heat source (for aluminum). A torch may be necessary to
apply heat fast and evenly before the oxide reforms.
All in all, I'd try mechanical connections with a antioxidizing compound between
the two metals.

>Tony
>K4KYO
>
> <ras@us.net>

I haven't actually remoted a transmatch before, but based on my experience with other projects I would suggest:

-Replace rotary switches with relays. Either one SPST relay for each postion on the switch, or a binary tree of SPDT relays if the switch has more than 3 or 4 postions and the extra power and control logic to close more than one relay at once is not a problem.

-For tuning roller inductors, a screwdriver motor might actually be a good choice since it has lots of torque and turns reasonably fast. These are easily reversible since they use a permanent magnet DC motor. Their 2.4 Volt high-current requirements are not optimum for driving through a long cable though.

-Tuning of variable capacitors may be tougher since they only go 1/2 turn from minimum to maximum. A stepper motor might work here, but at the usual 1.8 degrees per step there would be only 100 steps from min to max. Using a gear reduction assembly like is sometimes used with a manual knob for precise tuning could help make final adjustments easier in the higher bands. Also, a nonlinear varaible capacitor like is used in old (and new, for that matter) AM radios would be useful for this, but I don't know if there are any built for high voltage.

-Stepper motors can be driven to intermediate steps for fine tuning, but the driver circuitry gets more complicated, although probably not prohibitively more so.

-Of course variable inductors and capacitors could also be replaced with a bunch of relays and fixed components. The SGC automatic units supposedly work that way. Not much use if you have the Transmatch already and want an inexpensive way to remote it though.

-For indicators, if stepper motors are used you just need to count the number and direction of step pulses applied. This technique needs to be synchronized by running the motor to one end of its range against a stop or limit switch and setting the counter to zero every time the count is lost (which will most likely be only if the power is turned off).

-Indicating the position of a shaft driven by a screwdriver motor is harder. Also you probably want some sort of feedback (either manual or automatic) to confirm that the shaft is actually turning. Attaching an optical encoder disk to the shaft would be one way. Attaching the encoder to the motor shaft (before the gearbox) would give really good resolution, but I don't think there's an easy way to get access to it in most of the screwdriver mechanisms. I have had some success putting Hall effect sensors on the outside of the gearbox to sense the passage of the gears inside.

-The obvious remote indicator is a potentiometer driven by the shaft. More mechanical work required to couple it on than there would be just counting pulses applied to a stepper motor. Also digital encoders would be nice if a digital computing device is used at the control head.

-Really old remoted stuff like radar antennas used selsyns or (other "syns" or synchros, I forget exactly what they were called) to indicate the position. One is driven by the shaft and alters the phase of an AC signal supplied to another one, which drives the pointer. Really neat, having continuous resolution over one turn. Probably could be found surplus if you look, I think they are too antiquated for most catalogs. I'll bet the military still uses them in a lot of stuff.

-Another method of indication would be to temporarily remotely disconnect the capacitors and inductors from the circuit and remotely measure their capacitance and inductance. This could be done with an oscillator that uses the component as part of its frequency determing network feeding a frequency counter at the remote control head. I would classify this technique as "experimental" and maybe not too practical since you would need to turn the transmitter off in order to take a measurement.

I've worked VK and Europe on 160 SSB Mobile. I wonder if my being so angry when I was driving in traffic has caused my antenna to be a cross field antenna? Seriously, does that mean my antenna is great? I think not. The measured efficiency is around 1 percent, so who I have worked is no real proof of a great antenna or a remarkable invention, and neither is a patent. 73 Tom

Dave, I use a spec anal and a noise generator to test passband circuits on occasion. It has the advantage of having a log scale. My sweep generator is the most convient for linear measurements (in voltage not dB).

Either method would allow you to try different loading resistors as you watch the passband ripple, but you would have to use bridging pads, transformers, or active devices (like a JFET) to "bridge" the loading resistors.

Have you done the "trickier" part you mention. The reason I ask
is that I am planning to do the same for a rig I am building. I
will be using the 68HC11 u-controller. I would be interested in
hearing any comments or suggestions that you might have.

There's no such thing as "type acceptance" for ham gear other than HF power amps. The only FCC approvals needed for a VHF or UHF HT are under Part 15, for the receiver and (in some cases) for the microcontroller if used.

Hi,
You didn't say how much you are willing to spend.
A real performer is the KK7B R2/T2 combination built for 2
meters. The R2 design was in January 1993 QST. (Receiver board).
The T2 design was in April 1993 QST (Xmtr board). An article which gives
circuits for VFO's for 2 meters and how to put it all together was in May
1993 QST (All by Rick Campbell KK7B.)
This will get you on 2 meter CW and SSB.
I think mine cost about $150 all together.

....lots of stuff deleted

I agree with Mike on most of the stuff. I built one with the help of a friend who understands digital servos and steppers and all that stuff a remote tuner needs. We used stepper moters from old 8" floppy drives, used the optical encoders from Digital Equipment workstation mice, the ones with two buttons instead of a ball. This allowed us to have dials to turn for the steppers.

The main disadvantage of the stepper is the number of wires required to control it, luckily I had a spool of 30 pair phone wire.

We found electric rotary switches at a surplus place, they do exist, these were 5 position 3 wafer switches fairly heavy.

Indicators was where we fell down, tried various methods and wimped out and used a rather unusual method that would be very expensive if we didn't already have a large junk box.

We mounted lights on the tuner to indicate the switch positions, and a little halogen light to illuminate the whole thing, then mounted a black and white closed circuit TV camera above it, with a monitor in the Shack. I use it to tune a pair of delta loops made from the guy wire of a vertical, fed with ladder line.

It works, was it worth the effort or expense absolutely not, but it was a fun project and I learned a lot. I have the contraption in the attic and the ladder line through the roof, and have nightmares everytime it storms. I will probably go back to the old method of ladderline throught the glass in a window and a manual tuner and alligator clips to connect it to the ground bus in the shack when it storms.

QST had plans that we based our design on in 89 or 90 I think, it was called either a Balanced balanced tuner, or a double balanced tuner. It uses 2 roller inductors, and two capacitors in either parallel, or series configurations. We of course had to tweek it to add other combinations that don't do much.

Good luck
KI5GY

I would suggest that you look for an AMECO TX-62 transmitter at hamfests. They turn up quite regularly here in Atlanta. And I have seen them in the Yellow Sheets. They go for about $30 to 50 bux and run about 35 watts output. If you can find the matching VFO, you have it made, otherwise you would need to build one or use crystals. Definitely usable on OSCAR, etc. The parts in these things are worth much more than the price they are commanding.

It's called "Microcap" by Spectrum Software in Sunnyvale, CA (which is
in Silicon Valley, if not the capital of such!).

This is a great program I have been using for years. I know many other
happy users. It is much easier to use than Intuit IS-Spice or Microsim P-Spice.
That is why they can get $250 for it, while P-Spice gives away their
eval version (you get what you pay for). If your time is worth anything,
get Microcap. If you're a starving student who never sleeps, get P-Spice
for free off the net.

A number of people have asked how to design circuits or systems w/ ferrite components. I am posting several key equations here that are of use:

Standard Design Equation for Sizing (Determining B, flux density max.)

```
E * 10^8
B(peak) = -------------
Wf * f * N * Ae
```

where: E = RMS voltage applied to transformer/core
Wf= waveform factor (sine=4.44, 50% square wave = 4.0)
f = frequency (Hz)
N = number of turns
Ae= Core's effective cross sectional area (cm^2)

Determining H, field strength max.

```
0.4 * Pi * N * Ip
H(peak) = -------------------
Le
```

where: Pi= the constant
N = number of turns
Ip= peak current (Amps)
Le=Core's effective path length (cm)

Determining N, number of turns

```
( L )
N =( ------ ) ^0.5
( Al )
```

where: L = inductance (nanoHenries)
Al= inductance factor (nanoHenries/turn^2)

Determining Po, power handling capability of a core

```
1.47 * f * Bp * Ae * Aw * 10^-3
Po = --------------------------------
D
```

where: f = frequency (Hz)
Bp= flux density max. (gauss)
Ae= Core's effective cross sectional area (cm^2)
Aw= Core's winding area (cm^2)
D = wire current density (circular mils/Amp)

Core materials good for high frequency power transformers (various manufacturers):
Reccommended frequency of operation is core specific (see manufacturer's data)

3C8, 3B7, 24B, 77, 78, 75, F, T, H7C1, N27

There's no such thing as "type acceptance" for ham gear other than HF power amps. The only FCC approvals needed for a VHF or UHF HT are under Part 15, for the receiver and (in some cases) for the microcontroller if used.

Well, that's what the rep. at Icom said was why he couldn't provide a mod to transmit in the rest of the 440 band. Was i not given good information? He did tell me where others could provide a generalized out-of-band mod, but that's not what i wanted.

>And, for my rig, there's no mod to get the rest of the 440 band without
>running the risk of transmitting out-of-band, e.g. it's all or nothing.

If you aren't taking the care needed to keep from going out of band, you shouldn't have gotten into amateur radio.

If i were designing the software, i'd put PTT lock on a per [memory] channel basis. I don't want to transmit in the OSCAR subband by mistake, either, and after doing that a couple times, i get those channels a repeater offset, so at least if i stomp on anyone, at least it would be some terrestrial user. I really try to be careful, but when my concentration is on driving, for example, i may not be able to look at the frequency for as long as i would like to, or other times, i might bump the rig without noticing. An HT doesn't ask "Are you sure?" like my computer does, when i try to do something that i might not have intended.

You can order the 8044 from Mouser Electronics. Their number is floating around the internet and they have a small ad in some of the magazines.

But did you notice the small comment on page 76 of QST this month about the chip from the Radio Adventures Corp in PA? It goes for 14.95 in single lots and seems to have a few more goodies than the Curtis chip. 2 ma awake and 5 micro amp sleep modes, etc. Their number is 814-677-7221.

Hi Clark... I have sucessfully used an Intel 8031 micro to control
a Motorola MC145190 serially programmed PLL chip.
Also used and 8031 to control the Kenwood TM-741/742 series of VHF/UHF
modules independant of the radio (same idea...serial programmed).
You basically need 3 parallel I/O lines...CLOCK,DATA and ENABLE.
Toggle the ENABLE line then clock the data in, i bit at a time.
The basic concept is not difficult but the trickier programming comes
into play when you want the thing to be frequency agile as well as
control a display and deal with input from a keypad or rotary encoder.
Let me know if you have any specific questions...

> VE3JHU

Hi Bill. I am in the process of doing the "trickier" part of the programming. I've been held up with work, fatherhood and other domestic obligations lately but plan on getting back to it soon (hopfully) !
I personally know and use the Intel MCS-51 and Microchip PIC16Cxx families of controllers...not too familiar with the HC11 but my buddy designs aircraft radios using the HC11 as well as the Motorola PLL chips. If you run into any HC11-specific snags I could request his assistance if you like.
Of course, the programming concept is the same regardless of which controller is used. Have you decided what you're doing for display..ie.. discrete LEDs, Smart ASCII LCD or ??? How about input...keypad, rotary encoder, both ??? (easier solution...BCD thumbwheel switches take care of both display and frequency control but are not as cool, functionally or esthetically.)
You'll want to get the hardware sorted out before you delve into the programming.

Basically, the direct digital frequency is entered and stored in a working set of registers then each digit is multiplied by a wieghted constant and added to an accumulator... a cleared set of registers that represent the data word that the PLL understands as the equivalent to the actual frequency.
The wieghted constant will be different for each digit and are dependant on the PLL chip that you're using. This represents the BCD (actual frequency as entered) to Binary (the binary word that the PLL wants to see) conversion.
Once the accumulated value for that particular frequency has been tallied, it can be clocked into the PLL to set the frequency. This all occurs in the blink of an eye, then the micro would go back and read the working set of registers and repeat the calculations and load the PLL if any change has taken place.

I have a port pin polling the PTT line, when TX is sensed, the PLL is loaded with the TX frequency before transmitting and when the PTT line is released, the RX calculation and loading takes place. In my case with the TM-741/742 modules, the RX frequency is 10.7 Mhz different than the TX frequency (the I.F.) so I have a seperate bank of RX and TX registers. The TX rgisters can be offset plus or minus for repeater split or left alone for simplex. (I'm using the 2 meter FM module.)

You didn't give too much detail of what your are doing and using so I won't elaborate any further. I may put what I have done for the 8031 and these modules up on the local FTP site for anyone that might want to have a look. Lemme know if you're interested.

Regards...Hugh VA3TO...Toronto

Yes. Unfortunately that was done by hardcoding baud into the regulations instead of simply being satisfied with a bandwidth specification.

>which the frequency shift is one half the signaling rate in bauds"
>[ibid., p 19-30], i can't seem to find out much more about it than
>that.

There is more to it than that, however. Simply cranking the shift down on ordinary FSK to 1/2 the baud still leaves a fairly wide spectrum. The modulation has to be coherent to take maximum advantage of the spectrum conservation offered by MSK. A typical way to generate it is with a pair of four quadrant multipliers operated in phase quadrature with the carrier.

>I guess FEC [ibid., p. 21-6] is like what us computer-folk
>know of as ECC, a fairly powerful technique...

FEC is Forward Error Correction, and basically means that information is coded into the transmission to allow the receiver to recover damaged bits without requesting a retransmission. Since the FEC information has to be transmitted on the channel with the data, it reduces effective

throughput on a noiseless channel, but because it reduces the need for retransmissions, it can in practice increase effective throughput on noisy error prone channels. There are a number of FEC techniques, some of them are identical to the common ECC methods used with computer memories, some are not.

>OK, so QAM is how Bell/CCITT would run 9600 over their voice-grade lines,
>but i'm not sure what QPSK is like. What escapes me is how any of this
>is relevant to a homebrewer...

QAM is Quadrature Amplitude Modulation. QPSK is Quadrature Phase Shift Keying. They are both methods of impressing modulation symbols on a carrier, and both have in common the use of four quadrant multipliers operated in phase quadrature to the carrier. For the homebrewer, this means that the hardware needs to contain a pair of multipliers, IE MC1496 or SBL-1, etc, and that they need to operate on the carrier with a 90 degree phase shift network feeding them. A pair of multipliers, or a pair of pairs of multipliers properly arranged, can be used to generate any arbitrary modulation on a carrier depending on the modulating waveforms used. In the proximate case of the GRAPES RF modem, a pair of MC1496s are fed with waveforms from a lookup ROM. The data is encoded by changing the lookup addresses to the ROM.

>even be convinced to look seriously at doing the programming.

TAPR offers a DSP card, and of course AEA has a DSP based unit. And
several of the DSP chip manufacturers offer (cheap) evaluation kits,
such as the ones from TI and Analog Devices, that can be used for this
purpose. The rest, as they say, is just software. The TI chip is most
popular, but I like the Analog Devices chip because it's much easier
to program.

>material on this? I've never gotten along very well with the local
>Postal Service...

I'm not aware of any on-line resources, but the Lowfers publish a
newsletter called The Lowdown, and articles have appeared in several
magazines, including Communications Quarterly, about their circuits
and efforts. The spectrum 160 kHz to 190 kHz is available to any
citizen with the restriction of 1 watt power and antenna and feedline
length of no more than 50 feet. No license is required (yet, the ARRL
is making a grab to make this a ham band and close it off to most
of the existing experimenters).

>Of course, we don't need analog filters at all with a DSP, and then one
>can use filters that don't do annoying things, like ring.

Actually, we do still need analog filters. The dynamic range of even
16-bit ADDAs is insufficient to deal with the mixture of strong and
weak signals present on HF. We still need analog filters and AGC to
tame those differences between the desired and undesired signals on
the band. But, with DSP, we don't need to do *all* of the filtering
in the analog domain. This relaxes the filter constraints and allows
us to avoid things like analog filters so narrow that they ring.

>
>Or i presume if we want to operate in the VHF region, we can play these
>same games, and use a DBM to get in and out of the desired band.

Only if we can preserve phase coherency. To apply the technique to
individual RF cycles would require the LO to be phase locked with
the source. In practice, this is possible but complex, normally we'd
use TRF receiver designs if we wished to do oversampling directly on
the RF waveform. TRF receivers fell into disfavor when superhets
came along because the superhet allowed a simple analog IF filter scheme
that won't work with TRF, and because the discrete circuits of the
day made TRF receivers prone to instability. That's easily solved
today with higher integration circuits, and we're doing the bulk
of our filtering in the digital domain, so the IF filter is no longer
necessary.

> Now we have a powerful
> technique indeed for separating coherent signals from incoherent noise. The coherent
samples add constructively, but the random noise does not, IE a

> separating desired coherent signals from a chaotic channel. It's the

> basis for the astounding weak signal performance of the NASA DSN.
>
>OK, but can i do it at home?

Absolutely. In fact about the only way you can do it is to homebrew
the necessary circuitry. The DSN uses atomic clocks as their precision
reference, but terrestrially we can use more mundane common clock
references. The absolute value of the clock is unimportant as long
as both transmit and receive are in sync. Any signal that can be
heard in common by transmitting and receiving stations can be used.
Broadcast transmissions are a good source of a common clock reference.
If both stations are in range of an AM or SW broadcast station, that
carrier can be used as the common reference. WWV is another source
of a common reference, as are the color subcarriers recovered from
TV-sat signals. (You can't depend on terrestrial retransmissions of
network TV signals anymore due to the near universal use of frame
synchronizers at the local stations, but the signals distributed
to the stations by satellite all originate from the same point,
and subcarrier recovered directly from a TVRO receiver will work
as a common reference.)

The common clock needed for coherent data recovery is much relaxed
from the common clock needed for actual RF cycle processing. For
data recovery, ordinary crystal stability is sufficient to keep
pairs of stations' data clocks locked together. For RF cycle
processing, either atomic references or a common external clock
source is required.

The GRAPES webpage doesn't have any technical data. That can be obtained from the referenced paper, or by ordering the manual for the modem direct from GRAPES. There is also a 1/2 hour video I produced that has the designer presenting the system in detail at the ARRL National Convention. The tape is also available from GRAPES.

: ahead of me, and I will not rest comfortably until I have checked
: each and every connection point in the electrical system here.

Imagine my surprise a few years ago when my wife mentioned, off hand,
that one of our wall switches was warm... Turned out that the electrician
didn't like to use wire nuts, and instead had used these little crimp rings
to bond wires together. Over time, any circuit with significant current
would corrode due to the relatively small contact area, which generated heat,
corroding it more, etc. By that time the black tape used to insulate the
joint was toast. Shortly after fixing that box, we got a reminder to check
the rest of the house *now*; a similar junction behind the smoke alarm down
the hall got toasty enough to set off the alarm. I found two others that were
well on their way, and decided to replace *all* connections with wire nuts.

Besides our sleeping better, the lights don't dim as much when someone plugs in
the hair dryer.

2489. FM demodutator - any good chips?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-16 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Jun16.113902.59449@ucl.ac.uk>
Source record: 112396

I'm looking to build an FM demodulator. Anyone aware of a decent chip to do the job?
I am *not* looking for the complete receiver (some chips have mixers, IF amps etc).
One book (8 yrs old) suggests the CA 3089, but I cant easily find this, and expect
there is something better available now. I want it for a communications receiver.
Any outputs (S-meter, tuning meter, AGC etc) other than the audio would be nice.

I was contemplating building from scratch, since I guess most are made for the
Hi-Fi market, where low distorsion, rather than sensitivity is necessary.

IF is 10.7MHz.

Hey Guys,
I'm testing out a theory about my 2510, but I need to find some parts first. The 2510 has a 50 watt MRF477 final with a 20 watt 2SC2166 driver, both have a casing style TO-220. I'm looking for a 100 watt final and 50 watt driver to replace them. They need to be the same casing style and be interchangable with the final and driver afore mentioned. If any of you know where I could order these parts, such as RF parts, or the part numbers, please E-mail me at spackard@slate.mines.colorado.edu. Thanks!

The Heathkit HF Transceiver SB102 with the SB650 (digital frequency display) operated (as I understand it) by varying a LMO from 5.0 to 5.5 and mixing that with a hetrodyne oscillator with various xtals for various bands. The SB650 display (as I understand it) read those two frequencies and one other frequency (a carrier oscillator, I think) and then calculated the transmitting or receiving frequency.

I have a SB102 and would like to build a digital frequency display, for transmitting and receiving. I am soliciting advice on the approach. Any suggestions or comments welcome. I have not ruled out a simple outboard frequency meter (but never having experimented in this area, I don't know the pros and cons of just sampling the input freq to the driver on transmit and the and the...hmmm not sure here what to sample in the receive mode. Thanks in advance. K3FIG...

2493. Sources for Cheap Double Sided PC board?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-16 00:00:00 UTC
From: tayloe_d@sat.mot.com
Message-ID: <1995Jun16.201319.6362@schbbs.mot.com>
Source record: 112400

Anyone know of cheap sources of double sided or single sided PC board? I use this as both my chassis and to build my circuits on.

I use the "ugly" method of construction where components to ground are used to support all other junctions in mid air. The unmodified PC board copper surface then serves as a solid sheet of ground plane. This method is very easy to work with, no etching required. ICs are mounted upside down, pins up.

Brand new G10 type PC board is fairly expensive. A 14" by 24" double sided sheet can cost about $30. If not full size sheets, I would think that there would at least be sources that have scrap pieces that could be much more reasonable in price.

Thanks!

- Dan Tayloe, WB0NVB, Phoenix, Az.

2495. Linear amps and purity of sine wave?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-16 00:00:00 UTC
From: rohrwerk@netcom.com
Message-ID: <rohrwerkDAADDE.5qw@netcom.com>
Source record: 112402

I'm wondering how well the cleanness of a sine wave carrier
(before low pass filtering) correlates with adequate SSB linearity.

I ask because I've been fiddling with a PA based on DeMaw's "10 watt
Linear" in "W1FB's Design Notebook". It's a pair of MRF475's in
push-pull, and bears lots of resemblance to the stages used in Motorola's
bulletin AN779. Have been using NTE236's as a locally-available substitute.

Now most of my low-level (Class A) stages give a close resemblance to a
sine wave up to their rated power, and clip cleanly at their limits. But
the above mentioned PA, with the original bias circuit, gives only about 4
watts with reasonable cleanness; above that, it looks god-awful, but a
peak still shoots up to about 9 watts (probably limited by my 1 watt
driver). Of course, this looks fine after filtering, but would this have
a snowball's chance in hell of measuring decently in a 2-tone test? (Which
I am not yet equipped to do, otherwise I would have done it :-)).

Adding an adjustable bias circuit (string of diodes to provide about 1.8
volts, feeding a pot which feeds a pass transistor) makes it possible to
get a clean sine wave up to about 6 watts, but of course at the price of
Class A operation! (About 2 amps idling current gives me no noticeable
change in waveform till 5 watts) Beyond this limit, the clipping is much
more smooth as peaks continue up to the 9 watt limit -- a sharply angled
flat topping making for a fairly "pointy" waveform, but muuuuuuch better.

My hunch says to use this amp in Class A for a nice driver for my CCI
140-watt amplifier (based on Motorola AN762), but it made me wonder if
class AB amps really look that bad on a sine wave before filtering! The
only other amp I had to compare was my Ten Tec Argosy -- with no filter,
the 5 watt driver (class AB) was real clean, and the 50 watt PA showed a
flattening with about a 45 degree tilt throughout the power range from 0
to 50.

I do this myself all the time and then turn it upside down and use the
board as a cover sheet for a chassis box.

My common tactic is the dumpsters of PCB fab houses or there are sometimes
big boxes of bare etched boards in the surplus electronics houses. Often
the stuff is drilled and through plated but not etched...

Good luck

> All in all, I'd try mechanical connections with a antioxidizing compound between
>the two metals.

Here's a trick I've used for years to solder copper to aluminum.
The trick is to tin the aluminum first *under oil*. Transformer
oil or a high flashpoint mineral oil can be used. Coat the aluminum
part with oil, sand or scrape the oxide layer away, and tin the
surface with ordinary solder using a large iron *right through the
oil*. The oil keeps oxygen away from the aluminum so that oxides don't
reform and ruin the connection. Once you've tinned the aluminum, you
can clean off the oil and solder normally to copper. This works great
for bonding a copper wire to an aluminum chassis, or for joining aluminum
and copper wires. You'll need a *lot* of heat, I use a 300 watt
American Beauty Iron, and the oil will likely smoke like crazy,
so this is best done outdoors.

There are special aluminum "solders" available, but I find the
above technique produces a better electrical joint. You've got
to get that aluminum oxide layer completely off to make a good
electrical connection. I find you can't do that with a torch.
The aluminum re-oxidizes too quickly while you're heating it
because it's not shielded from oxygen. A TIG rig might work Ok.
You might be able to flood the area with argon while scraping
away the oxide, and the arc torch would then supply tinning
heat. Working under oil with an iron is probably more practical
for most home projects.

You can use a mechanical bond, but even with NoAloX, the joint
will become higher in resistance than a properly soldered
joint as the aluminum oxidizes.

I like to be able to read the chip so I bend the pins out and
mount the chip right side up (except for ground pins)..

Sometimes I cut off the tail of the pins leaving just tabs
sticking out of the IC.

I recall seeing something on this in RadCom a few years ago. Apparently
Vero *can* supply "unrouted" Veroboard - I think it is single-sided, though,
with no strips - but only for orders of #250 minimum. Some companies
apparently buy it like this for prototyping purposes. Mine doesn't,
unfortunately, although we do a lot of RF prototyping.

2502. Re: High Efficiency MOSFET HF Transmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-17 00:00:00 UTC
From: Jim Potter <jpawi@roadrunner.com>
Message-ID: <3rtjbs$5hm@tierra.santafe.edu>
Source record: 112322

I have used power MOSFETS (4 IRF840 in parallel) to drive the cathode of a 3CPX1500A7 to achieve 40 kW pulsed rf at 2 MHz up to 1% duty factor and up to 100 usec pulse width. You might want to contact your International Rectifier rep to get info on their new low charge series, with about half the capacitance/gate charge of comparable devices. I have experience with some sample IRFPC60LC (600V 0.4 ohm on resistance) devices. I'm not sure when these are going to be in production, but sample quantities are available. You might also contact George Krausse at Directed Energy in Fort Collins CO. His company puts power MOSFET dies in VHF (i.e. very low inductance) packages and uses them as high voltage rf switches with phenomenally short risetimes. They also have advertised rf applications at high frequencies. I seem to remember 1 kW, 30 MHz, but can't swear to it.

It doesn't work well at all. The heat needed to tin the aluminum
will melt the foam. This will be true of any soldering method
of aluminum jacketed foam dielectric cables. Aluminum is just
too good a thermal conductor. This is even a problem with copper
jacketed foam dielectric cables, but copper wicks solder so well
that you can usually make it work without melting too much of
the dielectric.

The CA 3089 is still the easiest and cheapest FM chip I know. It always works,
and is easy to use.
You should be able to find this chip at any place like Digi-Key and other
parts supplier.

2506. Looking for GaAsFETs to buy

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-17 00:00:00 UTC
From: Stephen Schiller <schiller@adobe.com>
Message-ID: <1995Jun17.024051.3084@adobe.com>
Source record: 112326

Hi,

If anyone knows of, or is, a source for GaAsFETs
in small quntites (like 3 or 4) please let me know.
Preferably HP-made, but I will settle for anything at this point.
(These will be used to build some VCOs, one with a center
frequency around 2.5GHz and another with a center frequncy
around 3.5GHz. If you have some other parts for doing this,
I might be interested those.)

Thanks,
Steve

Also included is my latest real-time DTMF decoder demo DTMF_RT2.ZIP. It uses a PC and a sound card to decode incoming DTMF tones in real time.

Any SB compatible sound card will work. Previously, DTMF_386.EXE was incorrectly compiled, and some users couldn't run it. Hopefully more persons will try it and find it suitable..

I also have custom versions of DTMF_486 for persons with custom needs, such as home-made answering machines, serial port transmission of detected tones, etc.. Please email me for any information.

Thanks.

In article <TVR.95Jun15164837@cnmat.CNMAT.Berkeley.EDU>, tvr@cnmat.CNMAT.Berkeley.EDU (Tovar) says:
>Well, that's what the rep. at Icom said was why he couldn't provide a mod
>to transmit in the rest of the 440 band. Was i not given good information?
>He did tell me where others could provide a generalized out-of-band mod,
>but that's not what i wanted.

This rep probably didn't have good information. Icom does make land mobile gear which *does* have to be type-accepted as to its transmitter, so he may just assume this across the line.

The guys are steel and not insulated from the tower. In addition,
the tower base is also grounded. I can connect all those grounds as a
star which then connects to the star at the house, but doesn't the
tower + grounds constitute 3 loops in the tower star?

IE, if the tower is grounded, a guy wire is grounded, and connecting
each of those to another, common, star create a loop?

Thanks, Gary,

Larry

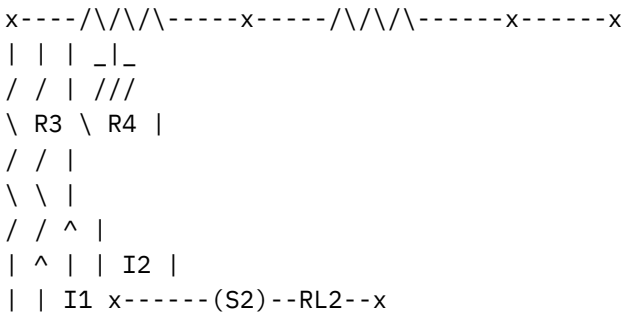
It's a circle, but it's not a ground loop. A bussbar represents a
ground loop, but it's not a circle. Confusing isn't it? The terminology
could stand improvement, as with the case of Earth and ground, they
aren't the same thing at all.

A ground loop occurs when two current meshes share a common
element. The current of one mesh modulates the potential
seen as "ground" by the other mesh, and hence indirectly
the current flowing in the second mesh. So the "loops" being
spoken of are current loops, not physical loops. And it
takes at least two current loops interacting in a certain
way across a shared impedance to create a ground loop. A
bussbar "ground" is a classic example of a ground loop.



```
| |
x-----(S1)----------RL1-----------x
```

Ok, R1 and R2 are the distributed impedance of the bussbar. R3 and S1 represent one piece of equipment, and R4 and S2 represent another piece of equipment. RL1 and RL2 are the working loads for S1 and S2 respectively. There are two current meshes. Current I2 flows through S2, R4, R2, and RL2. Current I1 flows through S1, R3, R1, R2 and RL1. R2 is the common impedance. Any change in I2 will be reflected as a different potential at the R1 side of R2, and will be seen as an elevation of "ground" potential by S1 which will alter the value of I1 flowing in that mesh. Any change in I1 will similarly show an elevated "ground" potential at S2. This is a ground loop. The potential of ground is seen as different values depending on the current flow in the *other* mesh. If lightning were to strike RL2, the value seen as ground at S1 would change dramatically, and likely cause damaging currents to flow through S1 and RL1, or between S1 and S2 if they share any interconnecting cabling.

If we eliminate the shared impedance by collapsing the buss to a star, the ground loop goes away.

The guy wires don't represent a ground loop because there aren't two current meshes.

```
x-------------(SL1)
/ | \ |
/ | \ |
/ | \ |
/ | \ |
/ | \ |
x-/\/-x-/\/--x--------x
|Rg1 | Rg2 |
|_____*______|
star
```

Where Rg1 and Rg2 are the impedances of the individual strips of Earth connecting the guy anchors with the tower base. These are shorted by the star connection and can be ignored. The current source is SL1 which represents a lightning bolt flowing current to Earth. The current will divide at the tower top, with some flowing down the tower, some flowing down one guy, and some flowing down another. The guys are in *parallel* with the tower between Earth and sky. There's only one current mesh, and no ground loop. The tower looks like the common element of our ground loop example above, but it isn't because all the currents are flowing in one mesh.

Now if the star were missing, and some piece of equipment's current mesh bridged a guy anchor and the tower base across Rg1 or Rg2, *then* you'd have a ground loop. Currents flowing

across Rg1 would induce a potential that would be seen in
the equipment current mesh, and alter the current flowing
through that mesh. By starring the grounds, we short circuit
that possibility.

>the rest of the house *now*; a similar junction behind the smoke alarm down
>the hall got toasty enough to set off the alarm. I found two others that were
>well on their way, and decided to replace *all* connections with wire nuts.

When using crimp ferrules, the wires are supposed to be twisted then
crimped. The crimp is only to assure the wires don't untwist. It's not
intended to be the only electrical connection. This is a secure wiring
method when done correctly. Normally, this method is only required on
safety ground wiring, but it is acceptable practice for other wiring if
extra insulation is applied.

Wire nuts often suffer from insecure connections too, and can be a real
hazard if not properly used. Electricians use wire nuts because they
are quick, not because they are good. Ferrule crimps are required on
safety grounds because they are good, even though they are a pain to
apply properly.

You suffered from an incompetent electrician, not from a faulty wiring
practice.

While on the subject of double sided PC boards, does anybody know
if double sided stripboards are available in small quantities,
ie 'Veroboards' with the component side covered with a solid
(well, punctured) ground plane. These would be ideal for mounting
DIL packages in RF circuits and possibly usable for mounting
MAR-n MMICs, since the impedance of the strip (or maybe two
strips soldered together) would not be very far from an ideal
50 ohm microstrip transmission line.

In an article in QST within a last few years, there was a construction
article with mentioned that a double sided stripboard was used to
build the prototype. Unfortunately, I have not been able to find that
article again.

>change in waveform till 5 watts) Beyond this limit, the clipping is much
>more smooth as peaks continue up to the 9 watt limit -- a sharply angled
>flat topping making for a fairly "pointy" waveform, but muuuuuuch better.

You should do ok in class AB or very close to B *if* the bias source is stiff enough. I've rarely been sucessful with a simple diode and pot circuit for more than one or two watts. The stiffer the bias source and the closer it tracks the device temperature changes, the less you need to waste power in standing current.

Be sure the devices you are using are linear devices also.

> It does, doesn't it. Believe me, the people who originated it take
>it very seriously indeed and spent a lot of time and money on patenting
>it. Whether it works effectively is a separate question.

True. Remember you can patent *almost everything* if you reckon
someone is going to bye it. Exceptions are plain perpetuum mobiles.

> The idea of simultaneously generating E and H fields is perfectly
>valid.

No antenna will radiate unless it generates (alternating) E and H
fields simultaneously.

>An antenna
>that really did create both would simply have no "near field" region
>with unbalanced E and H components.

This is where they are wrong. *Any* very small antenna, loop or whip
will suffer from it's low radiation resistance. The same applies to
the coiled mobile 5/8 antennas for CB.

>There is nothing that makes this *implicitly*
>inefficient, or troublesome.

Yes there is for all very small antennas: The need to transform
the feed point impedance to 50 Ohms is a potential source of losses,
and with the low radiation resistance of a few Ohms it would need
a perfect conducting ground plane to work efficiently.

> While this openness means that readers have to be selective, it
>provides a channel for occasional odd ideas and unusual approaches that
>can stimulate new ideas

Spreding new ideas is a good thing, but providing free advertisement
for those who try to get other's money by selling them junk, is mildly
said *naive*.

There have been the designs with the CA3089 in NBFM applications,
some of which worked, some not so well. Their main problem
is the low output and hence the poor signal to noise.
You can improve it somehow by playing with (increasing) the
feed choke to the discriminator, but do not expect miracles.

There are good reasons why newer designs use a 2nd IF at 455KHz.

Please excuse me if this is a stupid question but I'm new to this and I haven't been able to locate a FAQ for this group. I don't have a license, I'd like to learn code, and I've heard that the ARRL transmits code practice (I don't know the frequency). Does anyone know of any references to schematic diagrams that I can use to build a receiver to pick this up? Yes, I'm sure I could go out and buy a receiver but I really would like to build one (I enjoy building things, maybe some of you can understand that :). I do have some electronics experience so it only has to be a schematic but I'd like something quick & easy. Thanks.
- Steve.

Steve: I would suggest you purchase the 1995 Radio Amateurs Handbook or any previous edition of same. Besides haveing some simple receiver projects, the Handbook contains much technical and amateur radio information.

Also, take a trip down to your local library and see if they receive "QST" magazine which is put out by the Amateur Radio Relay League and contains many receiver projects.

They are in the Motorola Communications Device Databook. If anyone needs
the program to talk to the MC145170 I have a program that I wrote in
qbasic that uses pin1,2,3 of the parallel port. The program can be easily
modified to talk to the MC145190 and MC145191.

A rare golden bird - super condition!

Tektronix spectrum analyzer, composed of the following components:

- 7613 frame, selectable *storage scope* or normal trace
- 7A17 fixed gain amplifier plug-in
- 7L12 1.8 GHz spectrum analyzer dual-wide plug-in

- a spare 7603 frame, but display tube is non-functional

It's all solid state, in a standard Tek mainframe from circa 1980's.
The left of three slide-ins is taken by a no-frills, fixed gain vertical
amp. This is available as the left channel on the mainframe. The center
and right slot are the spectrum analyzer, and show as the right channel
on the display.

On screen dynamic range: top of the screen grid is marked REF and
the bottom division is marked -80 dB.

Sensitivity: picks up all the local TV and radio stations using a
paperclip on the input connector. The sensitivity dial spins around
to a minimum reference level of -100 dBm.

Tracking generator? No. It does, however, have 1st and 2nd LO outputs.
You'd need to externally mix it to generate a local version of the input
frequency.

Tucker sells just the 7L12 plug-in for $3995, but street prices seem to
check out at 1/2 to 1/3 of Tucker's --about $1300 for the 7L12 alone in
recent issues of Nuts & Volts. I offer the entire package for $1790,
including the second mainframe for spare repair parts.

Ok, now I understand. It's the common point obtained by tying the bottom of the guys and tower together in a star which changes the configuration from a loop to a "mesh". In turn by tying the mesh into a the star at the house entrance panel eliminates the loop which might be formed between the two stars were they not connected.

Thanks for the help, Gary.

>
>Ok, now I understand. It's the common point obtained by tying the
>bottom of the guys and tower together in a star which changes the
>configuration from a loop to a "mesh".

No. It's not a ground loop because there's only *one* current mesh.
To have a ground loop requires two (or more) current meshes that share
a common impedance. We'd have a ground loop if there were a *second*
mesh, that included some equipment we are trying to protect, that
shared a common impedance with the first current mesh. The common
impedance of the two meshes in this case would be either Rg1 or Rg2
depending on the topology. By connecting the guy grounds in star back
at the tower base, we drastically lower the value of the common impedance
and reduce any ground loop effects. If the star connections are low
enough in impedance, we can say we have effectively short circuited
the ground loop. The ground loop would still be *there*, it just
wouldn't have much of an effect because the common impedance would
be so small.

"Mesh" is just a way of saying "circuit" in analytic terms for
certain current paths. There's nothing more to it than that.
When we analyze a complex circuit, we break it into simpler
closed current paths and call each of those a mesh. We can
then analyze each mesh, noting any common elements with other
meshes, and then combine them all back together, using those
common elements as the interaction points, to get a complete
picture of overall circuit behavior.

A mesh with no shared common impedances with another mesh is
a closed circle, but it's not a ground loop. Earth is a giant
sheet resistance, however, and when we make a connection to
Earth anywhere, there will be a common impedance with every
other connection to Earth anywhere else. Mostly those common
impedances will be fairly high, and we can short them out by
doing a low impedance star connection between the points.

>In turn by tying the mesh into
>a the star at the house entrance panel eliminates the loop which might
>be formed between the two stars were they not connected.

Yeah. A star connection shorts out the common impedance needed to
have a ground loop. Note that we don't much care about absolute
potentials in any of this. We simply *define* one of our star
points as reference ground. All we really care about is potential
values *relative* to that reference point. If we arrange our
wiring topology right, we can keep those relative potentials to
a minimum.

In point of fact, *all* potentials are relative. We just aren't very used to thinking of them that way. We tend to take "ground" as zero volts, but of course it is only if we define it to be. And if it has any impedance at all, we can only define it to be zero at *one* point. That's our single point in our grounding system.

Let me take a moment to explain where the term "ground" came from. When we say "ground", we really mean *ground potential*. All potentials are referenced to this ground potential. This idea is modeled on the idea of a weight suspended above "the ground". The higher the weight is above ground, the more gravitational potential energy it has. The closer it is to ground, the less gravitational potential energy it has. When it is sitting on the ground, we say it has zero gravitational potential energy. We could have the weight suspended above a table, and the table would become "ground". Ground is the potential reference, the defined zero state. This concept was well known when electrical physics started, and the term "ground" just carried over. We shouldn't confuse it with Earth. Earth is a non-homogeneous sheet resistance. No two points on Earth have the same potential when currents are flowing between them. Earth is not ground, though we can pick a single point on Earth and *define* it as ground for some particular circuit. But we can also pick some point not on Earth and define it as ground instead, and we usually do because we can arrange for that point to be tied to other points via simple low impedance paths that can be easily analyzed and controlled.

>the coiled mobile 5/8 antennas for CB.

And let me add that modifying the radiator so the E and H fields are equal will not eliminate near field effects. Near field is the area where the antenna does not look like a point of radiation, instead it looks like the field comes from many points in space. If the cross field antenna *works* on the principle that equal E/H fields alone eliminate near fields effects they are full of ....stuff.

Mortz certainly appears correct in all his opinions and facts.

But someone please answer my question. What is this alleged "cross field antenna" and what is the theory? It sounds suspiciously like these "E field displacement radiators" or "Magnetic radiators" that allegidly eliminate losses.

Every worker develops his own tricks, of course. There is a problem
with yours for electrical joints. You have embedded aluminum oxide
in the joint. The brushing breaks it free of the surface, but doesn't
remove it from the joint area, and it becomes trapped in the solder.
This usually isn't serious for a mechanical joint, but it does raise
the resistance of an electrical joint. The oil in my method suspends
the aluminum oxide particles and keeps them from becoming part of
the joint.

If your torch is set for a reducing flame, it will tend to shield
the area from oxygen, but if you move the torch back and forth to

avoid hotspot burnthrough, the surface will become exposed to the atmosphere again, and can reoxidize before a layer of solder can shield it. It only takes a fraction of a second for the oxide to reform. A steady really soft reducing flame can minimize this because you don't have to move it around, but such flames are harder to control in tight quarters, and the slower heating allows high volumes of heat to conduct to distant parts of the piece. This can be a problem if heat sensitive components are nearby.

My method does have a disadvantage for HVAC work though. You *really* have to get all the oil off before joining the piece to copper or you'll have pinhole leaks at points where remaining oil droplets vaporize. A good strong solvent will handle that, but in these "environment friendly" days, a good strong solvent is getting harder to find.

I have messed around with 6C33s. Your proposal is
gonna exceed the plate dissipation of 100w per tube.
I would say, don't try to put more than 10 watts into the grid.
If you want a kW, try using 8 of them, each running 250mA
at 300v. Don't push them, they have grid-current problems
when you approach max dissipation, causing bias instability.

That's because it is a pair of those things, crossed to form an E
and a H field at right angles to each other. Since those things don't
really work, it's not surprising that combining them doesn't work
either. (Well, they work, just not very efficiently.)

Someone please give this poor boy (me) some advice.

I'm currently working on a homebrew J-pole antenna for 2m and 70cm use. Unfortunately, I do not own a SWR meter for the 70cm bands (none of my local amateur friends do either). However, one of my friends has a forward/reflected power meter with a 2m & 70cm slug in it.

I realize that I have to position the coax feedpoints to the J-pole radials in order to tune the SWR's to an acceptable level. I have access to a MFJ-249 antenna analyzer but it will only work from 1.8 to 170 MHz. I plan on using this instrument to tune the 2m portion of the J-pole.

I'm presuming that SWR's can be calculated from forward vs. reflected power measurements. The problem is that I can't locate any references to this subject in any of the local libraries. If it is possible to derive SWR's from this type of measurement, would someone be kind enough to provide me with a suitable formula?

Thanks in advance and 73,
Mitchell

DOes radio shack sell good fm transmitters like 5-watt ones or do they
even sell low-power tranmitters or kits? Anyreplys would be VERY accepted..

Please reply to ad161@detroit.freenet.org

Message-ID: <DADztG.F07@freenet.carleton.ca>
Source record: 112343

I am looking for a good 1-10 watt Class C transistor amp circuit for my
college Telecommunications course. The teacher is not a ham, nor is he
very experienced at building amplifiers (He admitted to me that he has
never built one.) Rather than get stalled de-bugging a troublesome circuit,
I am hoping that one of you clever people out there can give me some
advice on a proven design and help me avoid a potential disaster.
Thanks for reading my posting, and have a good day, eh?

>>> ADMIN
A compendium of all issues are available from ftp.cs.buffalo.edu as \pub\ham-radio\mlhackXX.zip, or on SimTel archives (eg. oak.oakland.edu) as \SimTel\msdos\packet\mlhackXX.zip. The XX in the filename indicates the last issue number, and replaces the previous convention of using mlhacker.zip for all compendiums.

Notice my email address has changed and the direct dial data line has been terminated. The administrative overhead of maintaining personalized "electronic superhighway" access has been too much. I'm hunkering down, and consolidating all my activity into one commercial account just like everybody else. I still only have regional access. If you have a recommendation about which national or international provider provides the most complete, powerful, and lucid text based access to Internet, I would love to hear it.

January through May have been quiet months - no MLH volumes were issued. Sorry about the delay to those of you who asked. No I haven't fallen off the face of the earth! February was vacation time for the family, driving across this great country one more time to visit friends and family. March and April were spent in Alabama at a military "middle management" school. May sort of dissolved into a lot of catch-up activity, and <poof!> I find it's already June. Time flies! August through December I expect to be busy at a military Space Tactics School. I'm not sure what network access I've have there. I'm sure I'll bring a small packet radio station, but I may not have Internet access.

>>> AUTOMATED PULLUP FROM THE BOOTSTRAPS
I don't buy lithium batteries anymore. When the NiCd batteries die, the entire RAM disk dies. I've developed some batch files that will rebuild the entire environment in under 3 minutes. I've used them for over a year, but now they incorporate the Stacker setup discussed in the previous issue. First, you need to make a removable disk with the following files:

```
CONFIG SYS 38 12-30-94 2:48a
AUTOEXEC BAT 128 12-30-94 2:20a
STACKER COM 47266 6-27-91 1:12a
SCREATE COM 2762 6-27-91 1:12a
SCREXEC EXE 38565 6-27-91 1:12a
SCREXEC2 EXE 27974 6-27-91 1:12a
SETUP1 BAT 257 12-30-94 3:18a
```

```
SETUP2 BAT 15 12-30-94 3:05a
SETUP3 BAT 102 12-30-94 3:16a
SCHECK EXE 30646 6-27-91 1:12a
PKUNZIP EXE 23528 3-15-90 16:52p
UTIL ZIP 84904 12-30-94 12:34a
```

Just power up the brain dead minisport (only disk C:), stick in the removable disk with these files and enter the command "A:SETUP1". But what's in the customized files? Below I list the name, followed by the contents of each file that isn't a .COM or .EXE file:

```
CONFIG SYS 38 12-30-94 2:48a
device=d:\stacker.com d:\stacvol.000
```

```
AUTOEXEC BAT 128 12-30-94 2:20a
@echo off
echo BjM (InCrea) P autoexec.bat
path c:\;d:\;e:\util
prompt $p$g
verify on
e:
set lfbrowse=l
set lfedit=ed
```

```
SETUP1 BAT 257 12-30-94 3:18a
c:format d:
c:label d:
a:screate d:stacvol.000 /s=1.2 /m
copy a:config.sys d:\
copy a:stacker.com d:\
copy a:setup2.bat d:\autoexec.bat
copy a:fastwire.cfg d:\
copy a:scheck.exe d:\
echo Auto warm boot to recognize disk E: and continue setting up.
```

```
SETUP2 BAT 15 12-30-94 3:05a
a:\setup3.bat
```

```
SETUP3 BAT 102 12-30-94 3:16a
e:
mkdir util
cd e:\util
a:pkunzip a:util
cd \
c:label e:
copy a:autoexec.bat d:\
d:\autoexec
```

```
UTIL ZIP 84904 12-30-94 12:34a
This file has zipped up version of your favorite utilities you'd like
copied into a subdirectory on disk E:, with automatic reference via the
MS-DOS PATH command.
```

>>> BREAKING INTO BATTERY PACKS
A standard ZA-1-2 battery pack is 13.2cm wide, 2.7cm tall, and 5.5cm deep. Orient it in front of you so the black round charger connection is to the left. The metal contacts are on the bottom, also toward the left side of the pack. The manufacturer's label is on the top. If you pull loose the manufacturer's label, you can reach into the battery pack and touch the thermal cutout switch wired between two of the five series cells.

If you want to do anything else (like replace a cell), you'll have to be more aggressive! The top section of the case has an approximately 1mm lip that slides down inside the lower case, all around the edge. Use a thick blade knife that won't bend. Slip it into the seam around the periphery of the pack, push inward and lift the handle of the blade upward to crack the glue seal in several places. The goal is to pull the lower case away from the inner lip of the upper case. My case had only spots of glue - three across the front, three across the back, one on the right and one on the left.

All the cells are lined up on the right side of the pack, next to each other, with no space between. The left 1.5cm of the pack contains a circuit board containing the three contacts showing on the bottom, the board mount charging jack, and a tiny surface mount 0.1uf capacitor. I didn't look on the bottom of the board because I'd have to desolder all three slide tabs to do so.

The cells are the same size as a standard C-cell NiCd battery. They all have solder tabs. I've had good luck purchasing new batteries from E.F. Yost & Co, 2211D Parview Rd, Middleton, WI 53562, 608-831-3443. If you replace one battery, replace all five of them using the same brand and model of battery. I'm a battery consumer just like you are, and don't like buying what I don't need. I even keep all my 1sees and 2sees out in the garage. Nevertheless, every time I replace a single cell, I'm back into the pack a few months later repeating surgery. My opinion.

Typical displays mix (add) the lowest IF (455Khz) with the selected L.O
(Band osc.) and mix (add) the LMO (5.5Mhz). This works for receive also.

In some cases you must subtract the LMO, but it's a matter of selecting
which product from the mixer. (Sum or Dif.)

>That's because it is a pair of those things, crossed to form an E
and a H field at right angles to each other. Since those things don't
really work, it's not surprising that combining them doesn't work
either. (Well, they work, just not very efficiently.)

Gary<

Gary,

I get it now (I think). Someone that doesn't understand EM theory took two
folklore antennas, a low loss *magnetic* radiator and a low loss *E field*
radiator and combined the two inefficient designs to produce a even less
efficient device?

Sounds like a innovative design. Nothing for something. ;-)

Certainly SWR can be calculated from forward power and reflected
power. Check the Transmission Line section of an ARRL Handbook
for the formulas, Or in case you don't have access to a handbook,

SWR = (1 + rho)/(1 - rho)
my *rho* is usually written as the lower case greek letter rho.
and
rho = the square root of (Pr/Pf)
where Pf = power in the forward wave
Pr = power in the reflected wave

Now that all that is done, there is usually an easier way to tune
antennas, Just tune for minimum reflected power. If you get to
zero reflected, the SWR is 1.
I have been doing this for years with good success since it is usually
not impoortant to me just what the SWR is, but I want it at a minimum.

In any case, by effectively shorting (bridgeing to a common point) the tower base and the three guy wires, eliminates the possiblity for ground loops, correct? Bascially, all grounds go to a common point (by the utility meter) and are starred out from there.

I'm going to have to do a little rework this summer. I've been lucky so far!

For the Gunn transciever, check the hamfests. I've bought equivalent parts for about $10 each. They're surplus motion detector heads from commercial door openers and security systems. Brands are Alpha, Solfan and others.

Newark Electronics sells 1n5139's. They go for about $5, I think. Newark has a $25 minimum order and will do credit cards. Newark's number is (800) 281-4320. Ask for a catalog - they carry a lot of RF parts.

Have fun!

moritz@ipers1.e-technik.uni-stuttgart.de wrote:

: No antenna will radiate unless it generates (alternating) E and H
: fields simultaneously.

Re-reading what I wrote, I think my phrasing was poor. I was trying
to say that a "mature" electromagnetic wave propagating in free space
many wavelengths from its source and any other body consists of an
orthoganal pair of alternating E and H fields, in phase, and with
amplitudes in the ratio 377 volts/ metre of E field for each ampere per
metre of H field. Close to an antenna, the fields are not necessarily
in their final amplitude relationship. It's rather interesting to use
small field probes to explore the close fields of, say, an operating
dipole.

: >An antenna
: >that really did create both would simply have no "near field" region
: >with unbalanced E and H components.

: This is where they are wrong. *Any* very small antenna, loop or whip
: will suffer from it's low radiation resistance. The same applies to
: the coiled mobile 5/8 antennas for CB.

Yes, this is what I doubted about the implementation of their
transducers, they look very difficult to drive efficiently.

: >There is nothing that makes this *implicitly*
: >inefficient, or troublesome.

: Yes there is for all very small antennas: The need to transform
: the feed point impedance to 50 Ohms is a potential source of losses,
: and with the low radiation resistance of a few Ohms it would need
: a perfect conducting ground plane to work efficiently.

It's really the combination of the performance of available materials
and the demands placed by small structures. I wonder if higher
temperature superonductors are possible?

: > While this openness means that readers have to be selective, it
: >provides a channel for occasional odd ideas and unusual approaches that
: >can stimulate new ideas

: Spreding new ideas is a good thing, but providing free advertisement
: for those who try to get other's money by selling them junk, is mildly
: said *naive*.

I'm not sure how much of that Sprat article was someone having fun,
but a bit of wire and some tin cans is not easily interpreted as making

money by selling junk, and I rather suspect that no-one was impelled to buy one of the much more expensive commercial versions.

: 73, Moritz DL5UH (ex GM4ZNQ)

^^^^^^

The propensity for a certain callsign to get confused begins to feel like an albatross round my neck :-) George printed G4ZNQ in the power meter article, and so 'ZNQ spread around the world.

> Eric Barbour
> GLASS AUDIO

Thanks for answering... If you're involved with some of the designs in Glass AUdio, you probably have lots more experience with these puppies than I do :-)

I don't understand why I would be exceeding the dissipation of the tube, but maybe I'm missing something (probably)!

The rating sheet I got (a poor one at that) shows the tube good for 60 watts (both units together) and a max plate current of 600MA. Nothing for plate input or grid dissipation or current. Other tubes are conservatively rated at more than 3 times their plate dissipation for input, so I used that figure for now.

My proposal was to run 300 volts at 500 or 600 MA for an input power of 150 to 180 watts. Class D (switching mode - square wave drive). The plate efficiency should be better than 90% (I'v run tubes like this before and get over 90% efficiency), so the plate dissipation should be less than 20 watts per tube.

For a KW, I'd use 6 or 7 (maybe 8) tubes.

Hopefully, I'll get away without neutralization (with the low impedance non-resonant driver and the fact that this is switching mode).... but that remains to be seen.

What is the best source for these tubes? They seem rather expensive. I'd like to pay less than $20 each.

Regards,
Steve cloutier KA1SI

I am going into the Navy in a month and would like to get rid of some of the I.C.'s and various other components my father has gotten for me at work. I'll Say this up front, I don't want very much for this stuff, just maybe enough to take my lady out for dinner. (COD only - you pay shipping.)

E-Mail me at:

westlyon@WORF.NETINS.NET

I have almost anything you could want. The list goes something like this:

1101A 256x1 OLD SRAM(50+)
1802 MPU(4)
146805E2 MPU(4)
2016 2Kx8 SRAM (15)
2102 1Kx1 OLD SRAM(70+)
239 VOltage Comparator
2716 2Kx8 EPROM (100+)
2907 Freqfuency to Voltage Converter(50+)
324 Basic Op-AMP (100+)
4011 Quad 2 input NAND (100+)
4012 Dual 4 Input NAND (100+)
40161 Binary Counter(100+) Just like 74161.
4093 Quad 2 input NAND SCHMITT TRIGGER(150+)
4538 Dual One Shot (75+)
4541 Programable Timmer (150+)
7403 Quad 2input NAND (100+)
7404 HEX Inverter Gates (75+)
7407 HEX Buffer - Open Collector (High Voltage) (75+)
7408 Quad 2 Input AND (75+)
7409 Quad 2 input AND Open Collector (75+)
7411 Tripple 3 Input AND (75+)
74123 Dual One-Shot (75+)
7414 Hex Schmitt Tigger Inverter (75+)
74180 9-bit Parity Generator/Checker (75+)
74192 4 - bit BCD Counter (100+)
74193 4-bit Binary Counter (100+)
7427 Tripple 3 input NOR (75+)
7440 Dual 4 INPUT NAND (75+)
7446 BCD to 7 Segment Display Driver/Interface
7451 Dual 2 Wide 2 Input AND-OR-INVERTER Gate (75+)
7476 Dual JK FLIP FLOP (75+)

H11AA2 Optical Isolator (75+)
74C926 4 DIGIT 7 Segment Display Driver with an on chip counter and latch

7 Segment LED Displays (Common Cathode) (500+) <- Yes, 500+.

I also have many misc EPROMs pulled from non working mother boards. Plus I have many ADC DAC's from various sources (Alot from MAXIM).

There are also some specialty one of a kind items I have. For example an SRAM that is shadowed by EEPROM. This allows you to save the SRAM's contents as you wish (AT 5 VOLTS.) This is a SIMTEK nvSRAM.

I also have a few of the famous FRAMs from Ramtron. These are truely NON Volital RAM devices (but you are limited to something like 1 Million read or write cycles.)

I would also like to get rid of my Data Book Library. I have full sets from Intel (1989) and National Semiconductor. (You haven't seen a data book till you see National Semiconductor's simple databooks - beats the heck out of Motorola's books.) Yes, I have a lot of Motorola books too. I have books from TI, SIMTEK, RAMTRON, LATTICE, DALLAS, AMD, NEC...

Also, I have 2 breadboards (Each contains 4 6" Individual Bread boards mounted on aluminum). I have Jumpers (LOTS) to go with them in a new plasic box.

Included in this one time deal I also have my componet boxes. The 5 boxes contain resistors, capasitors, voltage regulators, variable resistors, LED's, Switches, Connectors...

If you want everything ... it totals about 10+ boxes (12x12x18) in our shed.

There was an excellent article on a starter rig in April (?) 1994
QST. I almost built it, then opted for my own design.

The band is from 160 to 190 KHz, needs fancy antenna to work at
all well. Not much activity around here (SE NY) either. Good luck,

Pierre Thomson KA2QPG

I have used ugly construction extensively and it a great way to build
things. It's so fast and easy compared to laying out and etching a board
that there is no contest.

For IC's, I drill the pattern for the IC (and countersink around the holes
to avoid inintended grounds), then insert a wire-wrap socket. The
components are soldered on the pins wich stick out the "other" side of the
board. the wire wrap pins are a little sturdier than the IC pins, and can
be (gently) bent into useful positions. Also, if you smoke the chip, it's
easy to pop it out and out in a new one.

I built the ARRL "High Performance Communications Receiver" the ugly way,
and it works great.

2566. CW MORSE Shareware for Contesting Previews

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-21 00:00:00 UTC
From: s009jap@discover.wright.edu
Message-ID: <3s7s71$vrh@alpha.wright.edu>
Source record: 112273

A small group here plan to enter a TI DSP Solutions Student Cosntest that has
a $100K worldwide prize... (see http://www.ti.com under challege keyword)
If TI accepts our entry we plan to have sharewaer hopefully by 9-30-95...

Part of my interest in this is to do a CQ WPX CW Contest Stattion that would operate
in the M/S class category & do multiple contacts concurrently.. in the past I have posted
about it... know we paln to do a small section of it. There will be 5 RX with one TX
share in a TDM fashion in a lan fiberoptic campus enviroment. One we can do CW reception
with allmost
human proficiency we would like to offer this as shareware... the targets DSP all have to
be TI per
their contest rules & depending on $$ we may try first the tms 320 c50, then the c30, and
c40...
since the wsu perhaps might let us use them.. but there is another team here that will be
entering the same contest.
we are basically independent & have formed a student org. (wsue-it) to pull this design off
before 12-25-95.
If anyone in their company works could lend teh c30 or c40 type boards & other development
utilities it would
be good to know who you are since we may not be able to use the equipment from the EE or
CE/CS dept. here.
It would be on a loaner basis...

market research question: what would be a suitable shareware registration cost? $15,$25,
$35 range?

tnx

2567. MicroCap Evaluation Version?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-21 00:00:00 UTC
From: blombard@bb.iu.net
Message-ID: <3s7v16$eo@cc.iu.net>
Source record: 112274

I'm looking for info from someone who has, or knows about, the Microcap evaluation version. They say that it can handle 25 nodes for $250. Do they mean that the total of the main circuit and any subcircuit that it calls has to be 25 or less? Or do they mean you can model a larger circuit if you break it up into 25 node subs?

If they mean the first case, how can you do anything with 25 nodes? I have a filter I'd like to model, but the opamp macromodels have more than 25 nodes each! And I need two opamps to model it.

Suggestions for another simulator that can handle more nodes (maybe 100?) would be very much appreciated.

Tnx es 73,
Bob

It always amazes me just how confused things get. I never "strongly
recommended" any spice program. I did mention, with disclaimers of not having
tried, two moderatly priced packages. HOWEVER, SPECTRUM SOFTWARE WASN'T ONE
OF THEM. Methinks that someone is trying to phony up some product
recommendations to increase sales. Let's have a little more care (or perhaps
a little more honesty).....73 Jay

2573. Building a Home! (Now that's home Brew...:) (Suggestions?)

Newsgroup: rec.radio.amateur.homebrew

Source record: 112280

Hello everyone,

I saw a thread a long long time ago about putting stuff in a home that was going up to make a Ham's life easier. I'd like to dredge that thread back up again since my parents are currently building a house. (Don't worry, my father is really interested in getting his license, and agrees we should do stuff now before it's too late).

I remember some talk about conduit, and also about grounds etc... If anyone can tell me about anything that they have done to make their life easier (when they built their home etc.), I'd really appreciate it!

Looking forward to your messages!

Source record: 112281

Continuing... I have my own 15 watt Motorola Maxar 80 radio (800 MHz) that I will be using on District frequencies (I am a disaster planner for the District). I will also be making emergency antennas for 25 watt mobile radios (that we may wish to pull out of their installation for use outside, for example). I hope for plans for 1) an omnidirectional antenna (e.g., the length and diameter of a wire I should use off the end of a coax connector, and the size of the ground plane), and a directional antenna (quad? yagi?) for use on the bus that goes to an outlying community, for use from my home to the District, and for use by a couple of outlying schools. Any suggestions would be appreciated. Also, is 50 ohm line standard with 800 MHz? Respectfully, -Tim KC6WGD timstep@cello.gina.calstate.edu

HI,

I think the CA3089 or 3189 is available from maplin ut you will get low s/n as it's primary purpose is for broadcast WBFM.

Suggest you look at something like the MC3357 or MC3359. They have a built-in mixer to convert down to 455kHz, so all you need to add is a 10.245 Mhz crystal, a murata ceramic filter plus a few R's & C's...

Have fun !

probably such things as making sure there's enough electrical service in the ham shack. running 220 V there as well as 110. maybe even a separate breaker panel in the room itself along with a kill switch for room power.

maybe a raised floor and a drop ceiling so cables and stuff can be run around and still make the place look tidy.

deep shelves...

that's a start, i guess.

I think I paid less than $50 for the student version of MicroCap.
That was about a year ago. It sounds very much like what you are
calling the evaluation version.

I have modeled several active filters using the student version
which have included up to 3 OpAmps. I don't think the macromodel
nodes are included. At least not the ones in the standard library.

You might check the book store at your local university for
MicroCap and I have also seen some inexpensive spice simulators
and texts.

Yup.. How about placing GOOD grounding rods THROUGH the poured foundation. You might have to add a few feet to the rods to make it work, but it should be a real great ground.
Also, make a window-like thing for antenna leads, etc... What I'm thinking of is kinda hard to explain, but it would go through the wall outside the normal windows, have a slide open/shut feature, and be adequately weather-stripped, but still accessable.

Of course, the most important thing is access to the kitchen.....

8^)

Good luck!

I am looking for plans to build a 2 meter and 70 cm walking stick beam. This is the one where the beam elements are removed from holes drilled in the PVC boom and then stored in the hollow PVC boom with some end caps when not in use.
If you have some plans or know where they can be found please post a reply or e-mail directly.

Thanks for the help. I have been looking for the plans for quite a while.

Byron

My "shack" is in one of the bedrooms that is used for my shack/office (well,
shack/homework headquarters. ;-)

I run my antenna cables through the vents up underneath the eaves, through some
attic space and down through a small hole that I've cut in the wallboard of the
ceiling in what used to be the closet. I took the doors of the closet off and
have a desk and shelves set up in there for my radio stuff. It is like the ham
stuff is recessed into the wall. Just route the cables through and underneath
the insulation. No pain, no strain... and the wife doesn't see any holes in
the "wall". Ha!

> Of course, the most important thing is access to the kitchen.....

Or better still... one of those mini-refrigerators, and a Mr. Coffee... ;-)
right in the shack!

The Microcap Student Edition is published by Addison-Wesley. A paperback
book with a diskette in a pouch. The book is sparse, as it's expected
to be used in a class with some sort of teachers manual. There's a fairly
restrictive shrinkwrap license, for what that's worth.

I've got the Microcap III version that cost somewhere around $40 a
couple of years ago. I've see Microcap IV on the shelf at the
local schools bookstore.

It has op amps models built in, so each op amp connects to 3 nodes.
The node limit in this version is 30.

I have a lot of fun blowing it up with math exceptions. It's sensitive
to the node order.

You can get older spice version (2G6 ?) for both MS-DOS 386 machines
on a Simtel archive ftp://oak.oakland.edu. Or for Linux on the
sunsite archive. The sunsite package has the users manual in a file.
(I've not got around to using it.)

Allen,

I'll be building a house in the next 6 to 12 months. The
future QTH is happily called "HAM Hill". The house will
contain a ham shack room.

The main goal I have is letting my wife watch TV or be on
the telephone without any interference from running legal
limit on bands 160M through 1296. Here is my ides on the
subject.

Exterior construction will use stucco (here in
California). With stucco construction I intend to solder
all that chicken wire together and ground it! Hopefully this
will help with the neighbor interference.

The telephone wiring will use shielded wiring. 75 ohm hard
line for the TV antenna, NO PRE-AMPS! Possibly considering
running conduit to/from the radio room.

The radio room of course will have 220V and 110V. It will
have a near shield room effect. This is accomplished by
using that thin sheet metal (or corrugated metal roofing
material) between the wall studs of the room (of course all
soldered and grounded). The flooring will have a layer of

sheet metal or even better copper. All this because the room will be on the second floor.

The coax will be pre-run inside the radio room walls to where the antennas are going. All the pre-run coax will be 1.25 inch hard line.

Anybody's comment is welcome as I'm still developing ideas. Also someone with experience in improving shielding and interference from just plain overload (not harmonics) from the radios would be great!

Source record: 112291

This is just a wild one... but if you haven't put on the roof yet, you might consider laying in some wire or sheeting just under the shingles (with connectors into the attic), so that you could just run up a spike for an antenna. How much? I have no idea. Just a thought.

Consider a beefy power line into the office/ham shack. My laser printer caused my lights to dim as it cycles. I suspect that "real" ham rigs would do the same (I wouldn't know, as my ham shack is a 2m on my belt).

Best of luck! de Tim timstep@cello.gina.calstate.edu

I built my own converter and transmitter several years ago and was able to work 20 miles or so reliabily.

Here in the Atlanta area (a quiet rural county) I can copy beacons near Macon and Cape Haiteras (sp??) so I can hear stuff a hundred miles to two hundred miles away on my ICOM 751A. I think contacts might be few and far between unless you get a buddy on.

2590. re: WTD: 2 M Walking Stick Beam

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-22 00:00:00 UTC
From: Michael.Black@juxta.mba.org
Message-ID: <545_9506221730@mba.mba.org>
Source record: 112297

byron_hellewell@out.trw.com (Byron) is looking for plans for
a 2m and 70cm beam that can be taken apart and the elements
put in a the PVC boom for storage.

First of all, plenty of small 2m beams have been described in
the ham mags over the years. I've even seen some meant to be
taken apart for portable use. There was the "Two-Toter for Two"
in QST back in June or July or August 1971. A while later, a
simpler and easier to build version was described, under a
similar sounding title. I think one of them showed up in
at least one of the ARRL books, maybe the FM and Repeater Manual.

I think I've seen some other easy to take apart 2m beams described,
but I can't think of them right now.

70cm beams have also been described over the years, and the smaller
size of the elements makes building them even easier. I don't recall
seeing any article about building a take apart model.

I can't think of any article off the top of my head that detailed
a combined 2m and 70cm beam, let alone one that is meant for portalbe
operation.

The point to all this is that you've described quite well what is needed
to mechanically build a beam that can be taken apart. Instead of
searching for plans, why not create it yourself? Find an artcicle
that tells you how to build the type of beam that you want, and
modify it so it is easily broken down. Certainly you don't need
someone else to tell you how to buy a piece of PVC tubing for the
boom, and how to screw on the end caps, and in many ways that is
what would make the thing portable.

I once was given a piece of electrical cable maybe four feet long.
It was for high current, and had quite a few strands of thick copper
wire inside. It's lasted me twenty years for times when I've needed
some thick wire; I havent' bought a soldering gun tip in all that time.
Anyway, The wire is easy to work with, though it's not sturdy enough
to last outside in the weather. For a temporary beam such as you want,
it might work well and has the advantage that it's lighter than some
metal. I was going to say that you could fix a bolt to one side
and then thread the other side when it came out of the boom (and that
would be your removeable piece), but it would be a drag to thread
that length and also to have to turn the nut off and on. Needs
some other mechanical fastening method.

Or you could use coat hanger wire. Again, it's easy to come by
and relatively light. I find it really hard to bend and cut, though.

For the trouble involved, just make a 1/4 wave vertical. No coils,
simple tuning...

The evaluation version is a full functioned and libraried package with documentation identical to the full-on package. While the limitation of 25 nodes can be limiting in some circumstances, like a Level 3 model, or even a FET that may have as much as eight nodes, the circuits can usually be simplified with time or voltage dependent switches for FETs or the Level 1 op amp models, unless every single operating characteristic of an op amp is drawn into battle when you consider this filter. I have successfully designed resonant mode and current mode switching regulators, complete with snubbers, coupling coefficients of ferrite cored transformers, slope compensation, loop gain and phase margins. Bench built prototypes worked first pass from the 25 node limit modelled design.

MicroCap, as an organization, does not discriminate between an evaluating user and a fully paid commercial user when giving tech support, and they are generous with their time in any case. My take-home on them is that they are seriously intent on helping everyone who calls. I would recommend them unreservedly, but you really need at least the eval version...Some SPICE reading in general is a major help.

2593. Dutch legislation - Info Wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-23 00:00:00 UTC
From: jurgene@eeb.ele.tue.nl
Message-ID: <3se480$lr1@tuegate.tue.nl>

Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.homebrew

Hi,

Im planning to build/purchase a wireless RS232 modem to connect 2 PC's over a distance no more than 200m. Does anybody have any experience in this kind of communications? Also, I would like to know the legislation concerning low-power short-distance tranceivers in the Netherlands. (Power/Frequencies...)

Hallo,
Ik ben van plan een draadloze RS232 modem te bouwen/kopen om 2 PC's te koppelen over een afstand van max. 200m. Heeft iemand ervaring met soortgelijke zenders/ontvangers? Ook zoek ik informatie over de wetgeving / regelingen op het gebied van korte afstand tranceivers in Nederland. (vermogen/frequentie-banden/keuringen).
BVD.

Hi

I'm new to this group, and have been watching it for only a week or so.
I wonder if there is a FAQ available. I'm planning to start learning
morse so that I can get my license. I also want to build my own receiver,
and maybe a transmitter late on. I would be happy if any out there could
help me with schematics, PCB layouts, etc. for radios. Hints and guidelines
for constructing my own equipment are also welcome. I want to start with
frequencies below 100MHz.

Sinserely

2595. how to isolate HT from auto power spikes?

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-23 00:00:00 UTC
From: reinerp@panix.com
Message-ID: <3sf230$re4@panix.com>
Source record: 112302

I'm powering my HT from the cigarette lighter, and although there are no
problems with noise, I'm afraid of volage spikes from the
alternator or starter blowing out the radio.
Would it suffice to put a 35 volt Metal Oxide Varistor in paralell
with the radio, or do I need a sink resistor somewhere also?
There *is* a fuse on the lighter plug.
Thanks for any advice.

jeffa@pax.ssd.loral.com (Jeff Albom):

>[good design equations]

>Core materials good for high frequency power transformers (various
>manufacturers): Reccommended frequency of operation is core specific
>(see manufacturer's data)

>3C8, 3B7, 24B, 77, 78, 75, F, T, H7C1, N27

A frequently misunderstood point about using ferrites is that there are several uses in which they're operated well above their "recommended" frequency range. Generally, the "recommended" range is the range of frequencies over which the core is relatively low loss (high Q). In broadband transformers, high Q isn't necessary and, in fact, is often undesirable. So "low-frequency" ferrites are often used for this application. At high frequencies, "low-frequency" ferrites (e.g. Fair-Rite 70-series) look more like a resistor than an inductor. But the impedance per turn squared is high. As long as the impedance is high enough, it doesn't matter that it's resistive instead of inductive. The impedance stays relatively constant for several decades of frequency instead of rising to a resonant point then dropping, like a good-quality inductive winding would.

Another HF application of "low-frequency" ferrites is in EMI suppression. The ferrite presents little impedance at low frequencies, but looks like a resistor over a wide range of higher frequencies. This makes it quite free of resonance effects and ringing which would occur if a high-frequency ferrite is used.

One other point. The resistive nature of "low-frequency" ferrites at high frequencies means that they're lossy. If the current through the winding is low in value, as in a properly designed and applied current balun, the loss is small. Poorly sized, designed, or applied baluns can overheat at high power levels due to excessive current. If you look at the manufacturer's data for impedance and calculate the amount of heat for a given current, you can see that when a "low-frequency" core overheats due to the resistive loss at HF, the flux density is way below saturation. Overheating of cores is frequently blamed on saturation, but at HF is almost always due to other causes.

Why Gasfets? They are expensive for the job u want.
Better to use a trannie like BFR91/96 or maybe even a mimic!

Whats the VCO - I maybe able to help further

Hello Jim,
Pinouts are: pin 1: no connection
pin 2: input +
pin 3: input -
pin 4: ground
pin 5: ground
pin 6: V out
pin 7: V source
pin 8: bypass
This is for the National Semiconductor LM 380N8 as detailed
in the D/A/T/A Digest so there was no additional explanation.

Enjoy!

If you were on this side of the big water, I'd suggest getting
the ARRL Handbook, or even joining the ARRL - lot of suggestions
for new hams in their newsletter QST. But even though you are not -
you'd probably still find the Handbook and QST very informative.

I did that and it works, but I would like to get some gain. Most of
the repeaters I want to reach are marginal with the 1/4 wave.

I should mention that the final antenna should be invisible, since
my appartment complex has a 'no outside antenna' policy. The
1/4 wave I have now is made of about 36 guage berylium-copper wire
and 4 lb fishing line. The ground plane is the steel box that the air
conditioner sits in (protrudes out from the building). The fishing
line runs from the top of the 36 ga radiator to the gutter, holding
it vertical.

Try the following pinout :
1: no connection
2: input, through 0.1uF cap.
3,4,5 ground
6: output,22-100uF to the speaker, plus 2.7 ohm and 0.1uF, in series,
from output to ground.
7: +12V power
8: 22uF cap connected to ground.

SNIP...

Added gain will not be significant going from 1/4 wave to 3/8 wave.
If you are looking for added gain go for 1/2 wave (hard to feed due to
high impedance feedpoint)
or 5/8 wave (easy to feed - a series coil will do the trick)

Hi Peter,
Back in the "olden days" when cellular first arrived on the scene, we had many problems with equipment getting popped by spikes during starting conditions, esp. in cars with maintenace free batts. The only sure fire cure we found was to disconnect the A+ to the equipment when the car was started. Needless to say the customers were not a happy bunch, but I think you might have a bit less trouble with a cig plug. Others here may have a better solution.

Roy does a good job here of clearing up a common misconception. However,
let me add that this advice applies only at low power levels. For high
power transformers, such as output transformers in power amplifiers, it
does matter whether the magnetizing impedance is resistive or inductive,
because resistive loads dissipate power and heat up the ferrite. Inductive
loads cause relatively little heating. In a 6 meter KW amplifier, you
will find that low permeability ferrites will heat up much less than high
permeability ones (that look resistive) even though the high permeability
ones have higher impedance.

Gosh, I wish you'd have asked last week. I saw a dealer last week at the Monroe Michigan hamfest that had several types of finger stock. I wasn't looking for finger stock so I didn't pay that much attention. He had several samples mounted on a display board. I believe it was one of the wire dealers that frequents most of the hamfests in the area, SE Michigan, NW Ohio.

You might try calling some of the wire dealers that advertise in the various magazines. You might get lucky. I'd limit the calling to dealers in Ohio, Michigan and Indiana.

Good Luck!

I just bought a Heathkit HW8 with a problem. The main variable capacitor has its Aluminum plates detached from the brass shaft. Does anyone have any advice on how to reattach them? Will heated brass expand enough for me to insert the almuminum plates easily? It's a dual section unit, with only 2 movable plates/section.

Well, there are a few areas where doing it right while you're building the home can make things a lot easier later. From the bottom up, here are some things to consider.

Do the ground field now. If you are going to have a slab, either at ground level or as a basement floor, make it into a Ufer ground. A Ufer ground is simple to do but a little hard to explain. As you know, Earth is a lossy sheet resistance. The greater the number of contact points you can have, the lower the resistance of the resulting connection (resistors in parallel have a net resistance lower than that of any individual resistor). The Ufer ground works in two ways to achieve this.

First I'd better describe what a Ufer ground is. It's just rebar in concrete. You want all the rebar in the concrete electrically connected together, and a connection to that network brought out of the concrete for your use. One inch diameter rebar is preferred. Twenty feet of it can handle lightning strike currents. More footage is better of course.

Concrete is generally a better conductor than soil, due to the ionic content of concrete. So you have this large somewhat conductive slab in intimate contact with somewhat less conductive Earth, and the slab in turn contains a network of metal bars in intimate contact with the concrete and available for your connections via the terminal point you brought out.

Now the slab conveys charges to Earth in two ways, first by direct sheet conductance, and second by capacitor action. The latter is most important for RF while the former is more important for low frequency and static charges. Since the slab is large, it makes a much better Earth connection than a few driven rods (resistors in parallel again).

If you plan towers, install the bases and radial ground systems now while the backhoes and concrete trucks are available. Also dig the trenches and lay the conduit for any cable runs between the towers and the shack. Don't forget a rotproof pull rope in the conduits.

I'd also recomend a perimeter ground be installed in addition to any other grounding you do. This is just a 2/0 bare copper wire buried all the way around the house, out about 4 feet from the foundation. This will tend to equalize potentials across the house in the event of a nearby lightning strike.

Now remember, *all* Earth connections must be tied together in *star*, no daisy chains. Think about this layout while you are planning it. It will be convienent if your ground window can serve as the star point. But if that isn't practical or desirable for some reason, make it possible to run a straight heavy conductor from the Earth terminal star to the ground window. Outside the ground window, it is acceptable, and often desirable, to make a star of stars when laying out the grounding plan. Don't let this happen *inside* the ground window, however.

Now on to the house itself. The first thing I would do is specify 2x6 wall studs instead of the typical 2x4. This has several benefits while costing very little extra. First it allows more wall insulation which will cut down on your heating and cooling bills. Second, and of interest to hams, it allows fairly large conduits, 4 inch, to be placed in the walls. Third, it makes the house stronger (couldn't hurt, right?). Again, don't forget the pull ropes. Plan the conduit runs to make establishing a ground window simple.

Now for other generic wiring, you should establish a wiring closet in the house. Run all telco, CATV, home automation, network, alarm system, etc cabling to this wiring closet. Don't daisy chain from outlet to outlet, bring everything back to the wiring closet in star. This will make it trivial to reconfigure if you add phone lines later, decide to subnet, want to rezone the alarm system, or just need to troubleshoot wiring problems. Run more wires than you think you'll ever need. They still won't be enough.

Power. There are never enough outlets, there are always too few breakers. Put in more outlets than you think you'll ever need, and use more breakers than you think you'll ever need. Use heavier gauge wire than the Code requires so that you can upgrade outlets and breakers later if you find you need more power to a certain location, IE wire for 30 amps even if you only intend to use 20 amp breakers now. Wire is cheap, putting it in later isn't.

For the ham shack, remember you want a separate power feed here, with its own master disconnect, and arranged so the power feed passes through your ground window for suppression. A complete subpanel is best, with 220 and 110, for both the amplifier and the rest of the station. (Note any *other* wires that enter

the ham shack have to pass through the ground window too. That includes telco, network, alarm system, etc. DON'T MISS EVEN ONE. That's all it takes to ruin your entire protective plan.)

Use GFI outlets in the ham shack and the workshop. They may save your life one day. Of course follow Code and put them in wet areas like the bathrooms and kitchen too. If you're feeling rich, put them everywhere. I think individual GFI outlets are better than GFI breakers, some electricians may disagree. Regardless, insist on GFI outlets on the hamshack side of the ground window, the GFI breakers back in the main panel will be ineffective past the ground window.

Figure you'll want to add a coffeemaker, a microwave, and a small refrigerator to the ham shack one day. Leave space and provisions for power for these vital necessities. A bathroom should also open immediately off the ham shack.

I could go on and on, and often do, but this hits the high spots of what you should be thinking about.

Gary

There is a complication in calculating the power when the output is sinusoidal. The anode voltage is varying from saturation to some higher value during the time the grid is pulsed to Vgmax. The wider the pulse with respect to the rf period the more dissipation. Of course the power output goes up also. There is some maximum efficiency, just like normal class C operation. This will occur somewhere between 90 and 180 degress of on-time. (For normal class C maximum efficiency occurs at around 140 deg. conduction angle.) You can calculate the grid and anode dissipation by looking at the constant current curves for the tube. Both the anode and grid current vary along a line of constant grid voltage during the fraction of the cycle that the tube is on. From the tube power input you can calculate the power output and the power dissipation. Essentially all power produced at harmonic frequencies is dissipated in the tube. My conclusion from the 40 kW amplifier (which I recently beefed up to 60 kW) is that the efficiency is somewhat less than with sinusoidal drive, but the simplicity of not having a grid/cathode tuned circuit was worth it.

Source record: 112240

My databooks are getting a little long in the tooth and
I need to find a suitable modern hybrid amplifier module
for a project I'm designing. I need to take a +11 dBm
linear signal to somewhere in 10-30 watt range. I've found
a module that will do 30 watts with 3 watts drive, but that
means I need an intermediate amplifer. I'd be happier with
a single module that would go from 10 mW directly to 10 watts
or so. Alternatively, I'd be interested in hearing about a
module that will bridge the 10 mW to 3 W gap. Anyone have
any suggestions?

Gary

My previous post must not have made it through. (were having trouble with
the server or some provider somewhere) My question relates to
transievers, I am new to radio and need some direction. I am currently
building two 2600 BPS modems (using the EXAR chipset XR-2400 with
XR-2443 microcontroller) These are standard telco modems, but I am
adding audio in and out jacks. Can I connect these directly to audio
in/out of the transiever? If I used a 9600/14.4/28.8 modem could I
connect it directly? What frequency should I look for? What price
should I expect to pay? I am building 2 to set up a communications link
between two devices through standard serial ports. I have heard
*some*thing about a TNC, is this for packet radio? With my setup will I
be able to access packet radio? Ack, I am confused. Will this require
an FCC license, if so where can I get a book to study for it. I need a
reange of a few miles, but if price is too much I can settle for around
500ft. Are there any FCC regulations against encrypting my signal? Can
I keep it up for extendad periods?

That's enough questions, I would really appreciate it if you could Email
me at site@xnet.com, thanks!
```

DON'T BE ANNOYED if you've seen this before.
I am going to troll with this for a few days.

Also, EXCUSE ME for length of this post.

TO: SOME SMART PERSON
FROM: Dave Allen, Falls Church, VA (allent@mnsinc.com)

Vehicle: 1988 Chev Conversion Van
Engine: 5.7L w/ TBI-220
History: 82K Miles
- - - GM Target Trans at 61K July 1993
- - - A/C currently inoperable (believed to be unrelated)
- - - No maint other than routine

****
Problem: High Idle - 800-1000 RPM in gear; 1500-2000 in P/N

Bottom Line: Do I want to mess with this? Do I have a choice?
****
Background

This HI problem has been driving me nuts. Began gradually (esp in P/N) at 55-60K miles, after clogged fuel filter caused surging and loss of power. Shortly thereafter, transmission began failing, was removed, repaired and eventually replaced.

Prime Suspect: Idle Air Control valve

Recently cleaned & TBI bore. Ran service manual test of turning on key waiting 20 secs for Electronic Control Module (ECM) to command IAC pintle fully closed in TBI bore & disconnecting IAC lead (visual inspec shows bullet head to be sticking well into TBI bypass port). Started engine -- no effect. Idle cut-off set screw has no effect.

Cause of High Idle

HI can only come from too much air in manifold, right? If it's not IAC by-pass air, either a vacuum port attachment, the manifold (unlikely?), the TBI unit or its interface is leaking. Right?

Svc Man suggests very careful inspection for vac leak. TBI is heavily encumbered with accessories & 4-5 manifold ports for EGR, AIR, etc. I could not remove the rigid double 1/8 inch tube fitting at the port on the front of the TBI (for fear of breaking it); it appears secure. I was unable to detect leak, but possibly I was not looking in the right

place(s).

Lesser Suspects

Timing is correct & PCV valve appears OK. I am discounting leaky injectors; however, fuel consumption is up (because of HI?). ECM inputs for P/N switch, A/C relay, and O2 sensor voltage appear normal..

Without SCAN tool and getting no ALDL codes, am assuming ECM is properly commanding the IAC. At any rate, fully closing the IAC has no effect, so I am concluding physical/mechanical vice electronic/electrical problem. It this a correct assumption?

Possible Clue?

Throttle Position Sensor (TPS) voltage responsive and within specs Strangely, when spraying de-gummer agent around outside of TBI, idle dropped into spec when fluid was continuously sprayed around TPS/throttle shaft connection. Was cool spray altering TPS voltage or was fluid sucked into a vacuum leak around throttle shaft or other opening? Seems impossible to inspect this area.

Manual makes mention that *some* TBI's have *hidden* dust shields. Could these have deteriorated? Could TBI be leaking air elsewhere? I lightly snugged 3 manifold attach bolts. No change. Could the TBI/manifold gasket be leaking?

What to Do?

Since I can't get the vehicle to pass EMT with the high P/N idle speed, I suppose I will have to give up & put it in shop, but I hate like hell to admit defeat and assume the Ben Dover position when I SUSPECT it may be a *simple* fix.

3 questions --

1. Has anyone had experience that might provide a key to solving this problem?

2. Where can one go for info on this?

3. Does GM have a *service kit* for TBI's that might include seals and gaskets? If so, would it be a good idea to try this? Do I want to remove the TBI? In many respects it seems more straight-forward and simpler in design than a 4-barrel carburetor with calibrated floats & metering jets, etc.

Any thoughts/advice on this would be helpful. . An e-mail would be most appreciated.

For those interested, I would be happy to share whatever I learn.

>a 2m and 70cm beam that can be taken apart and the elements
>put in a the PVC boom for storage.

I built one, not that fit in the boom, but fit in a 2 foot long 2" diameter tube, that worked on 2m, 220, and 440.

Started with a heavy telescoping CB antenna, used the thick end and extended it out and cut off the small end to the length of the 2m beam. I took 3 pair of TV rabbit ears, built clamp-on rings to clamp to the CB antenna, and cut the rabbit ears so extended were the correct length for 2m. The rabbit ears had a flat mounting tang, so I was able to fold them back for storage. The clamp on rings were the only things that had to be fabricated, I cut 3/8" wide strips of 1/8" aluminum and bent them the right diameter for each half of the 3 clamps for the TV rabbit ears, then attached them with screws to hold the rabbit ears, but swival to store.

Anyway you should get the idea, then I found with a tape measure I was able to position the elements and lengths for 220 or 440, not as simple as just pulling out to full length, but it did work.

Just wander around in hardware stores, surplus stores and let you imagination take over.

I also have a 2m dual element quad that stores in a 4' 2" tube, be creative, that's the fun part.

Then there is my portable 80m 6 foot diameter capacity hat that fits in a Large coffe can, complete with loading coil.

: a module that will do 30 watts with 3 watts drive, but that
: means I need an intermediate amplifer. I'd be happier with
: a single module that would go from 10 mW directly to 10 watts
: or so. Alternatively, I'd be interested in hearing about a
: module that will bridge the 10 mW to 3 W gap. Anyone have
: any suggestions?

The Mitsubish M67712 only needs about 100 mW to generate
the rated 25 watts at 222 MHz from reports I've gotten.
According to the data sheet for this part, the gain is
just a little less (33 vs 34 W when driven with 300 mW).

A MRF 581 can be used to drive it cleanly with just a few
mW. The March 1994 QEX has a suitable circuit, though you
could probably do better with an "optimized" version.

A problem with the Rick Campbell R2 receiver design (Jan. 1993 QST)

Trying to run a bit of battery-powered Field Day from home, I was reminded of a problem I've had with my R2 receiver: the audio drops out very suddenly below about 11.9 volts. And I mean abruptly right at that voltage! This obviously creates problems for battery operation.

With my scope, I traced the problem to the LM387 audio preamp stage. The stages before this were still working below 11.9 volts.

Anything one can do to re-bias that stage or something? Or do I have a marginal chip?

>Thanks,

Hi Pat,
These amplifiers can often be 'pulled' (or tuned up) to the 10 Meter
band, but that's about it. The transistor matching networks are
always too high Q (narrow band) to support multiple band operation.
You'ld be doing good to get it to operate over both the sideband and
FM portions of 10M band at the same time.

Hope this helps,
Mike Groves KD6PKJ

Why not make the J Pole out of copper pipe then, using the appropriate
unions. It will look exactly the same once painted, and would have the
additional advantage of a flatter SWR curve due to some broad-banding.

2644. Looking for schematics/plans for homebrew TNC

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-26 00:00:00 UTC
From: negaard@draagen.graceland.edu
Message-ID: <NEGAARD.95Jun26163522@draagen.graceland.edu>
Source record: 112251

I'm looking for plans for a simple but reasonably-performing TNC.
I've got the skills to etch a board and build the thing, and I might
even be able to lay my hands on a PROM burner, but I need a plan/place
to start.

I'd _like_ one that incorporates or can incorporate a 'standard' modem
disconnect header, and I'd also like one that might be useful for
working PACSATs someday (with appropriate modifications, if
necessary). It would also be nice if it either had a state machine
DCD or used an XR-2211 (so that I could use the TAPR mod).

Any or all of these extras are negotiable. What's _not_ negotiable is
at least KISS capability (I'd use a Baycom, otherwise). I want to use
this with Linux, and KISS _might_ be all I'd need, but I'd still be
happier with more.

Any pointers/tips? I'm living on a budget that would starve a
field-mouse, so I'm looking to do things on the cheap. Any help would
be appreciated...

I have had NO PROBLEMS with the use of CB type amps on 80-10 meters.
The only problem is that the input impedance will become very low at
7 - 3.5 Mhz. This can be fixed by installing about 18 Ohms of series
resistance to the input curcuit. Or by using a cheap 200watt MFJ
antenna tuner. The second problem is that there are no output filters.
The second and third orders will be amplified. If your using a Hi-Q mobile
antenna the amount of power radiated will be very low at the harmonic
frequencies. Don't use a spider antenna without adding output filters.

By the way, most internal antenna tuners like those found in the Yaesu
FT-890/AT or FT-900/AT will not match the input impedance at 7 to 3.5Mhz
without the addition of these series resistors. I have a metron MB-1000B and
it too has series resistors in the input curcuit for this same probelm.

I had exactly the same problem about a million years ago (well, in 1979
or maybe 1980). The chip simply wouldn't realibly work off the
automotive power supply but was fine at 15V. I don't recall anything
could be done to change it; the issue is with internal bias sources.

You could use a voltage inverter (like the 7660) to pump up a negative
supply, maybe....

If your dad has a motor home, consider laying out the back yard and
garage so he can get the motor home into the back yard. Makes it less
conspicuous to the neighborhood. One acquatintance of mine designed his
garage with a 10' roll-up door on the front _and on the back_ of the
garage, so he could drive the motor home thru the garage. Also made
it easy to do work on other vehicles. He also had a 110v/220v outlet,
RJ-11 phone outlet, sewer cleanout and natural gas line in the patio slab
next to where the motor home would be parked.

>Now on to the house itself. The first thing I would do is specify

>hurt, right?). Again, don't forget the pull ropes. Plan the conduit
>runs to make establishing a ground window simple.

I'd specify 2x8s for the exterior perimeter walls. More insulation.
Lower heating & cooling bills. And specify that walls between bedrooms
and the adjcent rooms be 2x6, and fiberglass-filled. Makes it nice and

quiet.

>Now for other generic wiring, you should establish a wiring closet
>in the house. Run all telco, CATV, home automation, network, alarm

>decide to subnet, want to rezone the alarm system, or just need to
>troubleshoot wiring problems. Run more wires than you think you'll
>ever need. They still won't be enough.

Run the utilities underground from the pole to this room - i.e. the
underground conduit from the pole comes to this room. Read a
good book on EMP, and lightning, and incorporate what you learn
into the phone and CATV feed.

>Power. There are never enough outlets, there are always too few
>breakers. Put in more outlets than you think you'll ever need,
>and use more breakers than you think you'll ever need. Use heavier
>gauge wire than the Code requires so that you can upgrade outlets
>and breakers later if you find you need more power to a certain
>location, IE wire for 30 amps even if you only intend to use 20
>amp breakers now. Wire is cheap, putting it in later isn't.

20 amp outlets have one prong that is a "T" shape, the other is an "I"
shape. 15 amp outlets have two "I" shaped prongs. The outlets
themselves come in several grades, the top grade is "hospital" grade.
Specify the middle grade - the prongs are tighter, more metal in them.

Put a telephone jack everywhere you will want one - and pull at least
3-pair, if not 6-pair. The labor is the same, 1,000' of 3-pair
is under $40, 6-pair is under $70. Mount the RJ-plates in plastic
single-gang outlet boxes, and use 1/2" plastic conduit stubs into the
attic, with a pull rope. Use double or triple jack plates, and wire
two pair to each jack. Put an extra outlet box (with a blank plate)
on every wall of every room, with a pull rope. Home run every cable pull,
be it phone, TV Coax, alarm system, doorbell, stereo speakers, etc.
Use a telco "66" block to terminate the cables for the phone jacks
(called "inside wire" or "station wire" in the trade).

If you have questions about phone wiring, there was a long thread
about phone and home LAN wiring in comp.dcom.telecom recently. You
might post over there and ask if anybody saved it.

And put a extra phone jack on the front porch (under a weatherproof
flap), and by the back porch (ditto), and in the garage. Put a mini-
toggle switch in the wire closet to cut off the outside jacks.

A friend of mine in Phoenix AZ taught me the trick about the extra
boxes - they are cheap when done before the drywall goes up, and can
come in very handy. Since he moved in, he has used several: one for AC
power, because the couch blocked one outlet, another for a RG-58 run to
a scanner, and two others for phone jacks he didn't think he'd need

when the plans were laid out.

>For the ham shack, remember you want a separate power feed here,
>with its own master disconnect, and arranged so the power feed

>better than GFI breakers, some electricians may disagree.
>Regardless, insist on GFI outlets on the hamshack side of
>the ground window, the GFI breakers back in the main panel
>will be ineffective past the ground window.

I like GFI outlets in the bathrooms and kitchen - I saw a note once
that went something like "Nothing is more aggravating to a woman
than to get out of the shower, pick up the hair dryer, and have the
breaker pop, then have to go across the house, down to the basement
(dripping, and in a towel) to reset an <expletive deleted> GFI breaker."

>Figure you'll want to add a coffeemaker, a microwave, and
>a small refrigerator to the ham shack one day. Leave space
>and provisions for power for these vital necessities. A
>bathroom should also open immediately off the ham shack.

All of which make a nice contest station even nicer...
Don't forget the hide-a-bed couch in the ham shack.

>Any takers?

>shima@eel.ufl.edu

I think what you mean is you want to do an audio frequency
spectrum analyzer. A project like this was published in
QST a while back, but using a custom audio input, before
the Sound Blaser type boards became common.

Basically, what you need to do is calculate a Discrete Fourrier
(not sure about spelling) Transform or DFT at a number of
different frequencies. You do this by in software generating
sine and cosine waves at each of the desired frequencies. Then
you multiply each sample from the soundblaster by the sine and
cosine and store the results in seperate x and y accumulator
arrays (one element for each freq. of interest). Let it accumulate
for a little while, then calculate each magnitude by sqr(x^2+y^2).
Rezero the accumulator arrays, and do it again - over and over.

You'd probably need to write in assembly language, although C
might work as well. Getting it to run under windows would be
a real pain. The faster your computer, the more discrete frequencies
you can divide your band into. The tricky part of the coding is
remembering to subtract the DC offset of the input, and figuring
out a way to multiply the 2's compliment numbers. Fortunately,
you only have to take the square root one per frequency at the end,
in order to get the answer.

I'd write the program (I once tried, but didn't know enough
then to get it to work) but I don't have a soundblaster.

Well, I won't disagree with you on the "dirtiness" of many
"CB" amps (especially the more "garage-company" units).

BUT - I can tell you that many's the time I wish I had a
solid state amp for 10 meters, about 100 watts.....and can't FIND one.
Build one? Maybe, but from what I've seen you can wrap up a fair amount
of cash in that for possibly only smoke in return. I haven't that much cash
to risk.

Thanks to the crud from CB, it is of course a problem for anyone
to manufacture and sell 10 meters amps.....

Radio shack now sells a FM 2meter mobile rig, that is around 40-45 watts.
They also sell a 2m HT that puts out 1 to 6 watts.

I still cannot recommend what you are doing to others. You are asking
for problems. What happens to the gain of a bipolar transistor when
you move down in frequency? Uh, it goes up. Way up. Will your
amplifier stay stable with those very high gain conditions? It all
depends on who designed it. (Sorry, I just don't put much faith in
11M amp designers.) Do you even have a spectrum analyzer in line to
find out? Your bird watt meter wont tell you if you have spurs, but
the FCC will after they recieve a call. Harmonics are only part of
your concerns. Severe oscillations can happen quickly and are are
often distructive, then you get to witness a very expensive
flash-bulb.

Just a hint - calibrate the storage tube with marks for the settings
for the element lengths - it is much quicker than using a tape measure
and not as likely to get lost.

Well you are right, there are silicon transistors that could do the
job. But I haven't been able to locate a mail order, or surplus, source
for any of those either.

The fastest transistor I have found is an MRF901, which has an Ft of
around 4 or 5 GHz, and that is close enough to the upper range of one
of my proposed VCOs (4GHz) to make it hard to design a VCO with a *wide*
tuning range. But if you have some hints on how to do this I would be
happy to listen. (The purpose of these VCOs is to make a swept signal
generator from 0 to ~2GHz by mixing signals from 3GHz-2GHz VCO with a
3GHz-4GHz VCO. This, in turn, would then be used in a spectrum analyzer.)

Actually, I think the BFR91 is about as fast as the MRF901. Don't
know about the BFR96. I was looking for something with an Ft around
8GHz.

But I have to admit that another reason I was thinking of GaAsFETs is that I haven't used any before I wanted to get some experience with them. Someday I plan to build some equipment that operates at ~10GHz (radar stuff) where GsAsFETs would be more necessary.

2660. DDS & PLL Hybrid Theory

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-27 00:00:00 UTC
From: stratton@mit.edu
Message-ID: <stratton.46.01729045@mit.edu>
Source record: 112177

Direct Digital Synthesis is too noisy, and Phase Locked Loop
synthesizers don't have a small enough step size for HF use.
So it seems like a popular way to do things is touse DDS to
generate the frequency, but then use a PLL to reproduce a
spectrally clean version of it.

May QST had an article about a "DigiVFO", a DDS using 64
phase accumulator, but only 8 bit output fed to the DAC.
This was okay, because it drove a Drake rig that used
a PLL to clean up the VFO input. The Harris DDS code producer
chip acutally had 12 output bits, but only 8 were used to keep
the cost down.

By why even bother with 8 bits? The PLL compares the phase of
the local oscillator and the DDS (the reference). Why does it's
phase comparator care if the reference is a nice sine wave? In fact,
wouldn't it be happier with just a square wave? So why not use
a 1-bit DAC - ie, just feed the phase accumulator MSB into the PLL.

Re-arranging things conceptually, it seems that this is the
same as making a tradition PLL synthesizer capable of
non-integral division factors. That is, sometimes it divides
by int(f) and sometimes by int(f)+1 with the fractional part
being determined by the occurence ratio of the two divisors.

This seems to be about what a DDS does: the frequency desired
determines how much to increment the phase accumulator. At 360
degrees it rolls over to zero - but it won't actually hit zero
unless the numbers work out just right. Instead, the phase
samples actually used progress slowly each cycle. What
we're acutally doing is dividing the DDS clock by a non-integer -
by selecting an integral multiple of a tiny fraction of that clock.

I'm not sure if this argument makes any sense, much less if it
is correct. I would guess I'm missing something somewhere which
says that in the DDS/PLL hybrid, the DDS ouput has to at least look
like a reasonable sine wave, not a bunch of pulses that only average
out to being on frequency.

Anyone have any thoughts? I'm tryin to get my hands on the Harris
DDS code generator, and will see what happens with the MSB driving
a PLL - but if someone can tell me directly why this won't work,
it would save a lot of trouble.

How do most pre-amp manufacturers for the Amateur market (ARR or SSB Electronics, as an example) accomplish switching for mast-mounted RF sensing pre-amps?

PIN diodes or relays?

If relays, how do they get them to switch fast enough without burning out the active device?

If PIN diodes, what would be likely candidates for 2 metres or 70cm? I'm looking at in the order of 100 watts RF for satellite applications only, not EME where I understand sequencers and quality RF relays are the norm.

Are there any existing circuits available? (QST, RSGB etc)

I'm a little curious as to why multipyling 2s complement numbers
is tricky? I seem to remember that the '386 and up have an imull
instruction that does this nicely. Perhaps you mean "multipling
complex numbers"? That's a little more work, but not tricky.

I always thought the tricky part was getting the butterfly right.

Source record: 112180

Chris:
Here is the short answer to your question: In order for the DDS part to work correctly you MUST convert the DAC output to a sine wave!

You have missed a subtle part of how the DDS part of the combo works. The PLL uses the zero crossings of the phase reference to do the phase comparison. When the DDS is working much above about 1/100th of the clock frequency (and especially when operating at less (more?) than 1/10th the clock frequency) the zero crossings in the fundamental can occur without changing the most significant bit of the phase accumulator. Remember that the output of the DAC is NOT just the fundamental, but several harmonics and alias frequencies. These spurious frequencies need to be filtered out. This can be a good low pass filter if you want DC to about 1/8 the clock frequency for the DDS output. You can get REALLY close to 1/2 the clock frequency over a narrow range of frequencies if you use a narrow bandwidth band pass filter. The filter filters out the phase jitter that would be inherent in the DAC output. If you do an analysis of the codes that come out for low fractions of the clock frequency (say 1/3) you will see that the DAC output changes from positive to negative by some pretty weird values and these zero crossings do not necessarily correspond to the zero crossings of the desired phase signal.

My Mirage uses an Aromat relay, and I wait 1/2 second before I say anything
so the switching has happened.
>
>Are there any existing circuits available? (QST, RSGB etc)

Try the ARRL 'UHF Projects Manual'. For PIN diodes, you need to put
a 1/4 wavelength between the antenna and transmit terminals (I think !?!?!?).
You don't need to use an actual 1/4 wave of feedline, you can use
lumped elements.

>comparison.

The DAC output cannot cross its midpoint (zero of the AC output) without the MSB of the 8 bit word fed to the DAC changing. Thus looking at the MSB of the sine output (which IS the same as the MSB of the phase register (but 180 degrees delayed)) will give a square wave with the same frequency and zero crossings as the sign wave - but it will be loaded with harmonics

>If you do an
>analysis of the codes that come out for low fractions of the clock frequency
>(say 1/3) you will see that the DAC output changes from positive to negative by >some pretty weird values and these zero crossings do not necessarily correspond >to the zero crossings of the desired phase signal.

True - the zero crossings aren't right - but they average out over time to being right. Some sort of LPF is used on the DDS sinewave to smooth it out, and this has the effect of moving the zero crossings closer to the right place. But they won't always be right - so what effect does this have on the ultimate PLL output spectrum? And what would be the effect of greater average deviation in zero-crossing timing, ie, a 1 bit DDS output?

From: bon@paradox.win.net
Message-ID: <321@paradox.win.net>
Source record: 112186

I am trying to determine the current supplied to a network composed
by a resistor in series with a general impedance. The signal applied
has a wide frequency range (from 1MHz to 160MHz) and its magnitude is
around 2V. The magnitude of the current to be determined could be
from less than 2mA to 20mA. I have tried to get it, using a small
toroidal transformer with the primary created with a single wire
passing trough the center of the toroid core. The primary can not
have a strong impedance character. The results were not indicative
of a close end.
I would appreciate sincerely to receive any kind of information able
to provide me with a satisfactory way out of the problem.

The only plans that I've seen for "a simple but reasonably-performing
TNC" are for the TAPR TNC-2A. I purchased a bare board at Dayton 2
years ago. Came with the documentation and firmware on diskette.
You might want to contact TAPR and ask if they are still available.
Mind you, it's not really a "simple" TNC...it's a full blown upgradable
board.

Folks - re-posting to a spam does nothing but lengthen its life. You want to do something about the spammers (and I'm all for that), contact postmaster@wherever.com. The big online services (aol, prodigy) seem to produce the most spams (probably because they have the most users, and many of those are fairly clueless :-). The good side of that is that those big online services also respond very quickly to spamming problems originating inside their walls.

The current one we're dealing with did *not* originate there - it came from a site called "ixc.net", which means nothing to me, but I'm going to send an e-mail to the postmaster@ixc.net, just in case.

Why a TNC? You can build a PC ISA bus card with a z8530 SCC and you have
HDLC without TNC, and the drivers are distributed with the new versions
of the Linux kernel, and:

- You can get very high speeds if DMA is used (PI card).
- No eprom programming is needed.
- Some schematic about an opto-isolated SCC card (OptoSCC) are avaiable
(Sorry, I can't remember where are they)

And be careful if you plan to use one of those CB amps in a linear mode. The often are thrown together with no consideration for linearity. I would hate to see the Ham bands cluttered with some of the dirtiest amplifiers ever produced! Lot's (if not all) of the CB linear amps use no bias at all, others use very loose poorly designed bias circuits.

My opinion is that these CB amps should be left on CB, unless the guy doing the mod thoroughly understands what he is doing.

I remember seeing an ad for a program like that. There were
two versions of the product, about $160/$200 retail, but this
was two years ago.

It could function as spectrum analyzer both in real-time and
from a file. Runs under Windows. Real slick graphics.
Don't remember the title or the manufacturer, though.

Anybody remember who made this and what it was called??

>Basically, what you need to do is calculate a Discrete Fourrier
>(not sure about spelling) Transform or DFT at a number of
>different frequencies. You do this by in software generating
>sine and cosine waves at each of the desired frequencies.

It's a Discrete Fourier Transform, and it's WAY too slow. I have an FFT algorithm in C that is burning fast. I can do real time apps with it for 128 and 256 pt. transforms..

>You'd probably need to write in assembly language, although C
>might work as well. Getting it to run under windows would be
>a real pain.

Windows is a no no, but no assembly is required.. Optimal coding is all that is necessary :)

The faster your computer, the more discrete frequencies
>you can divide your band into. The tricky part of the coding is
>remembering to subtract the DC offset of the input, and figuring
>out a way to multiply the 2's compliment numbers.

Again, why do you have to subtract off the DC? The DC ends up inthe 1st FFT bin, just don't look at it if you don't want to! No need to further process it..

The coding is the simple part. The damn limitations of the SB is what is very annoying..

Go to your local hobby shop, get some brass tubing.
Cut off about an inch, and then cut a slit lengthwise in the brass. Now,
solder a piece of wire to the brass. Now, expand and force the brass
onto the solar panel. I did this, and it makes a good, damn tight fit.
Holds up well in inclinent weather also!

This would be a good idea. In addition, you could put a coil in seeries,
and a large cap in paralell with the power leads. I ran with an HT in
th4e car for a few years, and ran a couple of large electrolytic caps in
paralell with the power leads. (I had a dedicated power line from the
battery, with the caps near the radio.) I never had any problem.

Hi

I've given up finding any example schematics on the net via News, ftp, or WWW.
The result is that I have to design my own radio receiver.

Here is my plan:

```
Antenna -> Selective filter ---> Mixer -> Very selective filter -> Demodulator
|
VCO/Variable oscillator-
```

My assumptions:

1. The antenna delivers a uV signal.
2. There is a need for amplifying the signal from the antenna/filter
3. The selective filter is optional.
4. There are a lot of mixer IC's.
5. There are a lot of demodulator IC's available.

Are these assumptions OK?
I know general electronics, but I'm unexperienced in this field, so any
help will be appreciated.

Well, that is the basic idea, but the superhet receiver you
describe is a little tricky for a first project. A better bet
would be to start with a direct conversion receiver - a single
mixer translates RF down to audio and a little amplifier
drives your speaker. Once you get that working, you change its
local oscillator to make it receive at your desired IF frequency,
and then build a new mixer to get from your signal frequency to
your IF. Every time you add a stage, you add a tuned impedence
matching transformer and a bunch of stuff like that, so starting
simply with the Direct Conversion would let you concentrate on
one thing at a time.

Although it is not the highest in performance, the little Signetics
NE602 mixer/oscillator is a great chip to play with. In it's little
8 pin package, it has an oscillator requiring external L and C or
XTAL and a mixer - plus a little amplifier with quite a bit of gain.

For 40 meters a reasonable oscillator tuned circuit can be made
by taking a 10.7 mhz IF 'can' transformer (from an FM radio)
and padding it with an external capacitor - probably an air
variable - so that you can tune the radio around 7 mhz.
Alternatively get a T68-6 ferite torroid and wind (as a
starting point) about 27 turns of #22 wire around it.

For your audio stage, an LM386 amp works well.

It's good to build the circuit with the main tuning cap
mounted behind a metal front panel - othewise the capacitance
of your hand will pull the oscillator as much as a few Khz,
making tuning it nearly impossible.

Good luck and happy building!

I too have not had any trouble using solid-state CB linears 80-10
meters. I have only tried a couple, don't have lots of
experience with them, but many if not most of the CB amps
have the same sort of input/output broadband toroid networks as
the typical Ham amp has. As has been mentioned, harmonic
suppression is marginal but tuners can help both input and
output.
As for the older or current higher power tube amps they will
be quite narrow. I'm surprised at the comments received about
so-called linears not having any bias at all... I have seen the
innards of several cb amps and they all had biasing networks.
I wonder how much of these comments are from first hand
knowledge or just the typical ham-gut reaction to the nastiest
2-letter word ever invented? The noise and hash and splatter
that emanates from many CB linears results from the same thing
that causes it on the Ham bands.... non technical operators
overdriving them, one transistor in a push-pull amp being bad,
transmitting into an antenna system with open/shorted/intermittent
cable connections or otherwise highly mismatched, etc.

Not too difficult, depending on your expertise and test
equipment availability. Especially the UHV/VHF stuff marketed
by Ramsey and Hamtronics is relatively easy to build compared
to HF stuff, you just have to be a bit more careful with coil/
loop dimensions etc at upper frequencies.
I've built several HF and VHF linear amplifiers and at least in
my limited experience VHF/UHF is easier to build and less
difficult to troubleshoot.

f you've purchased a Kenwood YK-88 crystal filter recently, you noticed it's the same filter as always but now it comes soldered to a daughter board. If you installed that crystal filter in an older rig (TS-940, TS-440) you had to remove the filter from the daughterboard before you soldered it into your rig.

I want that daughter board and will pay $10 for one and I will pay the postage besides.

Contact me at jdonimi@uswnvg.com or call me at (206) 450-8395.

Well there- I was just repairing my Ft757GX, and had to replace a pair of blown 2SC2879's with a pair of 2N5942's in a pinch (no bux for new ones right now, and I had the 2N's in the junk box).

This got me to wondering- I have a Motorola RF data manual, which comes in VERY handy in times like this, but BOY would it be nice to have a Toshiba or equiv. "2SCtype" manual, showing all the stuff that Motorola shows in their databook.

It would make "repairing by the seat of my pants" a little more based on qualitative data than on- "well- looks the same... databook says it puts out about that much... wonder what the impedance is... what's the effect of running this 28V part at 14V... put on the safety glasses at power up...lets try and see :^)

THANX!

: LIMAUX%wema@wema02.elektro.uni-wuppertal.de

Yes, I have seen this IC in a Philips VGA monitor. It's a PLL to synchonize
the horizontal scan with the HSYNC pulse from the VGA card.

The pins are:
1 Output (Open colector)
2 GND
3 Sync Input
4 Sawtooth input
5 Phase Detector output
6 Regulator Voltage (A simple Zener regulator is included, so, connect
a resistor to your power suply (20 mA typical))
7 Oscilator Timing (with R to pin 6 and C to GND)
8 Duty Cycle control

From National Semiconductor Special Purpose Linear Devices Databook.

I hope this can help :)

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

A while back I posted a query to rec.radio.amateur.antenna and rec.radio.amateur.homebrew about using R-C lattice networks to provide a wideband Hilbert transformer (90 degree phase shift) for a receive antenna phasing unit. These networks are commonly used to generate the audio phase shift for SSB generation or detection.

I asked for a reference on how to design these networks. Yesterday, I received the June 1995 issue of QEX, which has a great article on these networks: "Polyphase Network Calculation usaing a Vector Analysis Method" by Tetsuo Yoshida, JA1KO.

Thanks to Tetsuo Yoshida for the excellent article, and QEX and ARRL for publishing this kind of material.

My next problem is designing a high-input-impedance, high-dynamic-range differential RF amp for the output of the phase shift network.

I've noticed the new JPS antenna noise canceling unit (which is a phased-array receiving antenna, intended to null locally-generated RFI noise) must use some kind of wideband phase-shift network, since it covers at least 3 to 30 MHz with only a two-position bandswitch: low band and high band. Has anyone opened one of these up? What does the phasing network look like? Is it a polyphase network? What does JPS use for an amplifier?

Thanks,
-Steve

: Chris, N1IIR
: stratton@mit.edu

Chris,
I only want to respond to one item in your posting, and that is
the mention of using a square wave from the DDS to drove the PLL.
I got caught by this a year ago, and it's because there is a
phase jitter term that comes into play. When using the MSB (square
wave) you will experience a 30-degree phase jitter. If you sum it
with the second MSB, it will become 15 degrees (I think I got that
right (?)). This is why we use 8 or so of the MSBs and then add a
low-pass filter to supress the clock feedthru.
Myself, I'm presently constructing a discrete 12-bit DDS for
the 10-Hz resolution fine-tuning in a receiver/transmitter I've been
working on. I'll be using the 8 MSBs, summing them with an R2R lad-
der, filtering with a LPF, and then through a schmidt trigger to pro-
duce a square wave for a PLL. The DDS acts as the reference signal.
I don't need to bother with the sine-wave conversion, but if I had to,
I would simply clip with a resistor and a couple of signal diodes be-
fore the LPF for some shaping, which will take carfe of the rest.
This method has its' limitations in terms of tunable bandwidth, but
for my application it's just right.

Anyone know of a small and inexpensive UHF (or better) tx and rx pair
that can handle a 1200 baud bandwidth link. Or schematics for such. I
have seen the stuff from Linear, but it won't pass anything better than
300 baud. Oh, this is a low power, 300' type setup (i.e., no license stuff)
and I believe that the 300 MHz used for wireless alarms and such falls into
this catagory.

That hasn't been my experience, Mike. Most of these amplifiers seem to be copied direct from the Motorola application note for a broad band 2-30 MHz 100 watt amplifier. The main problem with them is that they have little or no filtering in them to suppress harmonic radiation, just broadband transformers in and out. If you put a good output filter on them, tweak the bias, and watch your drive levels, they can be made into passably fair amateur HF amps for QRP rigs.

The tube amps, now, are generally adapted from a 1960s ARRL Handbook design, consisting of multiple sweep tubes in parallel. They're pretty hopeless. The huge parallel output capacitance of the tubes makes the output networks funky. Junking them out for parts is about all they are worth.

It seems to me the problem is that the gross steps are going to
introduce a lot of phase jitter into the PLL, IE mondo phase
noise, that would take an incredibly slow loop filter to handle.
So you'd lose all the advantage of DDS by doing this. The cleaner
the DDS output, the less loop filtering you need, and the faster
response time you get.

Lets see, now I believe we're talking about a Class D design here. The
tube is turned on hard during a very small part of the cycle, well under
90 degrees, and anode voltage will be clamped to Vsat during that time.
During the rest of the cycle, while the tube isn't conducting, the anode
voltage will follow the tank, and depending on loaded Q, can become rather
high, normally a peak to peak voltage 2x or more of DC plate voltage. We
can ignore that as long as the tube doesn't flash over. The thing we're
interested in is the current pulses we get from the tube during the time
it is saturated. The Rs of the tube will be Vsat/Ip while the power
delivered to the load will be tank Vt/Ip. So plate dissipation will
be proportional to Po*Vsat/Vt.

From: chuck62@freenet3.scri.fsu.edu
Message-ID: <3sr634$49c@freenet3.scri.fsu.edu>
Source record: 112216

I've got a Montgomery Ward SSB 40ch.CB I want to convert to 10 meters
if possible. The PLL is a NEC K8Y039 D2824C. It has a single 10.24 Xtal.
(I've heard that the single-Xtal PLL's are harder to do tricks with.)
BTW, all of the ads I've seen for CB modification books mention Sears,
Uniden, Cobra, Realistic, etc., but no Mont.Ward. Is this CB made by
somebody else (a clone)?
Lastly, can you recommend which CB mod. book (Screwdriver's Expert,
CB Tricks I,II, and III, Tomcat's Big CB Handbook, etc.) would do me
the most good for this rig?
...Thanks...

A friend of mine did the same thing, but used a 110v-24v transformer
as the choke - ran the +12 thru the secondary winding, then to the
+ end of the cap (2000 uf, 35v) then to the radio. It worked real well.
He used a fuse rated at one amp more than the radio manual specified,
and a LM 317 set as a 13v regulator, and a 15v 10w zener as a
just-in-case, lets-blow-the-fuse-NOW device.

It worked even better when he shorted the primary winding of the
transformer....

Given the recent discussion of MSB phase noise, that sounds a little too good to be true. Did you run the fourier analysis over many periods of the simulated DDS output? I would think the phase noise would generate a lot of close-in noise - in effect the 'signal' would be a narrow band of noise with a peak in the middle.

I'll have to try this experiment myself when I get home from work...

Message-ID: <3su9g2$2do@newsbf02.news.aol.com>
Source record: 112124

>>As for the older or current higher power tube amps they will
be quite narrow. I'm surprised at the comments received about
so-called linears not having any bias at all... I have seen the
innards of several cb amps and they all had biasing networks.
I wonder how much of these comments are from first hand
knowledge or just the typical ham-gut reaction to the nastiest
2-letter word ever invented? The noise and hash and splatter
that emanates from many CB linears results from the same thing
that causes it on the Ham bands.... non technical operators
overdriving them, one transistor in a push-pull amp being bad,
transmitting into an antenna system with open/shorted/intermittent
cable connections or otherwise highly mismatched, etc.
Jim WB5AOX<<

Jim, You haven't looked at the amplifiers from a micro level then. The
bias circuits are almost always very poor. They have NO regulation, and
that is what causes or aggrivates the excessive IMD products they produce.

For example, look at a typical 4CX250 B amplifier sold as a "Ham"
amplifie4r to CB operators. They almost always have NO screen regulation,
no control grid regulation (an absolute no no with any amplifier that
operates with grid current) and no metering.

Sweep tube CB style amps are often the same. They let the grid jump around
with the drive power. Flat-top and non-linear city....here we come!

Even the solid state amplifiers do not use active devices to source
constant bias voltages, so when the drive goes up the device moves into
class C!

I have *yet* to see a well designed CB amplifier, since the end user
demands carrier shift (forward modulation good buddy) with modulation, and
the very act of complying with this requirement means the amplifier is
pathatically poor in linearity.

CB amplifiers are by far and large absolute junk. They don't belong on
amateur bands unless the user understands the proper way to modify them
and that includes biasing as well as input and output circuits.

Steve,

I've been using phased arrays on HF since the early 80's. I use coaxial delay lines and cross fire phasing with broad band untuned loop elements. Some of the arrays have used as many as eight elements.

I am not sure why you would want to use a RC network for phasing. It does not seem like an efficient way to obtain phase shift (in this application) when coaxial delay lines provide lower attenuation and octave band widths (with proper array design).

Can you expound on the merits of RC networks in this application??

Chris:

You are correct about the MSB changing being when the DAC output crosses zero. Now let's see, where did I leave my brain? :<)

The problem is that there is phase jitter in the MSB changes. You are correct that they average out over time, BUT each individual zero crossing is VERY likely to be in the wrong place. (To paraphrase a famous TV guy: Can you say Phase Noise?). Any phase noise in the reference will be directly translated into phase noise in the PLL. The phase noise will be multiplied by the same factor as the ratio of PLL output frequency/reference frequency.

I would say one of your assertions differently. The low pass (band pass) filter moves the zero crossing to EXACTLY the right place (not just closer!). This is true, of course, only for ideal components. The amount of phase noise in the output of the DDS is a measure of how good your DAC/filter are. You were pretty close to the answer in your first post. A DDS output of 20 KHz with a clock rate of 4 MHz and 10 bit DAC will give a MUCH cleaner sine wave with almost no phase noise. The same clock frequency with an 8 bit DAC and a 1.5 MHz output would have a much tougher time holding down the phase noise.

I have been curious what effect settling time of the DAC has on spurs and phase noise. Theory pretty well predicts how far down the spurs will be from the fundamental for a given number of bits, but many have remarked that they have seen better results than theory would predict. I want to look into the possibility that the settling time amounts to a LPF inherent in the DAC. This would tend to reduce some of the higher frequency spurs.

Dana Myers (myers@West.Sun.COM) wrote:

: Isn't the usual case where the resistance is in series with the
: reactive components? In this case, Q = X/R; larger X gives a
: larger Q for a constant R. Of course, the R isn't constant,
: it goes up linearly as the turns on the inductor increase, but
: the inductance is proportional to the square of the turns; thus
: a larger L is better for high Q. I'd also guess using a larger
: L means that the smaller C required will also have a higher
: Q...

The loading is indeed parallel in general, however. Remember Rick's
suggestion that the load be tapped well down on the tank? This tapped-C
(or alternatively) tapped L arrangement is used as an impedance transformer
so that the tank sees a higher *parallel* resistance. Keep in mind that
it is the circuit *loaded* Q and not just the component Q that matters
here.

I guess the main problem with your argument is that you are talking
about component Q, not tank Q. When calculating the Q of a parrallel
resonant circuit, you must model the resistance in parallel with circuit.
The Q of a series resonant circuit is modeled with the resistor in
series.

When calculating *component* Q, you can model the resistor as being
in series *or* parallel. In fact, you can do a transformation from
one case to the other.

Consider a 1 uH inductor with 0.1 ohms in series at 1 MHz:

* The component Q is (2*Pi*1E6*1E-6)/0.1 = XL/Rs = 62.8

* The equivilent parallel Rp = Rs*Q^2 = 394.78

* Now you can compute Q as Rp/XL = 394.78/6.28 = 62.8

So I guess you could use your series Q formula as long as you
transformed the tank load to the inductor in series, and then
added it to the inductor's own series resistance, and then
computed the Q. Once you started considering your neglected
tank load term, I think you would reach the same conclusions
I did. For cases where the resonator is litely coupled into
the circuit (possible for high device gains), your analysis
is absolutely correct.

: >If large L's are used, the reactance goes up, the Q goes down, and
: >the phase noise increases, per theory.

I guess I should have used the term "loaded Q" here.

: See above. I'd guess that parallel loading of tank circuits
: isn't as much of a problem as the component series R.

Well, power *is* extracted from the tank, so you better consider it.
At low frequencies, where you can use devices with outrageous gain, then
the tank can be quite isolated. At higher frequencies, however, the
tank will generally see more of a load. Since the device gain is lower,
the tank will "see" the device input port more, since more power must
be coupled out of the resonator to keep the loop gain above unity.

: At upper UHF+, there are some neato ceramic resonators available,
: but they're kind of exotic for home experimentation as far as I
: can tell, since they have to be fabricated to the desired frequency.

These are coaxial structures that behave as shorted transmission lines
with a characteristic impedance of something like 6 ohms. They are
easy to work with: I am currently developing a modem product that uses
three of those type of oscillators. The small packaged 900 MHz
oscillators in cellular phones usually use them as well. The home
experimenter can build simular oscillators by using shorted sections
of hardline (but at a bit of a size penalty :)

If you can get hold of a resonator that is for a *lower* frequency
that you desire, you can in fact do some homebrew however:

1) Secure the resonator in a rubber Jaw vise, such as a Panavise, so
as not to damage the plating.

2) Carefully heat the center pin and pull it out with needle nose pliers.

3) The end of the resonator that had the center pin is not plated.
You can grind this end. This is best done quite slowly, with a fast,
fine, wet grinding wheel. Your fingers may be at risk if you are not
extremeely careful.

4) When you are satisfied with the length, solder the center pin back in.
Use 2% silver bearing solder.

5) Most of these resonators use a silver plating. Solder them to your
circuit using 2% silver bearing solder, or the silver will leech or
disolve into the tin-lead solder, ruining the resonator.

6) If you grind too far, capacitive loading can generaally be used to
place your oscillator back on frequency. It is typical to couple
a varactor or trim-cap in to the "tank" with a 1 pf cap. Tenths
of picofarads count.

Have fun!

First of all, get rid of the JFET. A bipolar is typically much
more temperature stable in the first place.

Second, ever heard of the Hallicrafters technique where you use
a differential type air variable connected in series with a P150
and an N1500 fixed capacitor? You can then continuously vary
the tempco till you hit zero.

Tap way down on the tank circuit with the transistor connections.
And use the highest Q tank you can get. Below 20 MHz., use a
Fair-Rite #67 toroid with a few dozen turns of fine magnet wire.
Above 20 MHz, use #68. Above 150 MHz, use an air core coil in
a shield can. Use a large L/C ratio in your tank.

The only simplification for the long and tedious process I know
about is the one used by E.F. Johnson for quite a spell way back when
in the 50s and 60s. They used a differential capacitor with a
neg temp coeficient on one side of the capacitor, and one of the
same value but a positive coeficient on the other side. The drift
was corrected by changing the position of the differential cap.
As I recall it still took some time to correct drift, but calibration
didn't change as well while correcting for drift.

I have seen about a dozen CB solid-state amps in the last few years. They were in the 60-100 watt range; NONE of them had any biasing networks. They were all what you would call "off-brands" I had never heard of before. (Probably made in someone's basement or garage.)

I built an HF amp from the Motorola Applicantion Notes a few years ago (the AN-762 amp.) This is an excellent amp that puts out about 140 watts for 5 watts of drive up to 30 MHz. Just need to make sure you put a LP filter on the output! IMO, this is the way to go!

From: Mike.Czuhajewski@hambbs.wb3ffv.ampr.org
Message-ID: <1995Jun28.234106.15237@wb3ffv.ampr.org>
Source record: 112133

The proper way to subscribe to the QRP list is to send e-mail to

listserv@lehigh.edu [do NOT send to qrp-l@lehigh.edu or
the entire list of over 500 people
and in the text say, will see it...and it will not get you
subscribed, anyhow :-)]
subscribe QRP-L

That's QRP-L, with an "ell" at the end. People always used to advertise it as "qrp-l", and that often caused confusion; some thought that final character was the number one (1). It is not case sensitive, and either way will work, but when telling someone else about it you should type it in upper case to eliminate confusion.

The mailing list also has a daily digest function available, which can be a god-send for some people, as it bundles all the days messages into a single e-mail message addressed to you. If you are not subscribed to the digest, you will receive a large quantity of mail every day, which causes problems for many people for a variety of reasons. Information on getting the digest will be included in the automatic "welcome" message you will receive shortly after subscribing.
Typical daily traffic averages well over 20 messages. (If you are on a system which charges by the number of messages received, the digest will help. If charged by the byte, it will not help.)

You are both "almost" correct here. A simple PLL can only filter out the higher frequency components of the MSB noise. If you have a relatively narrow band tracking filter on the signal going into the PLL, however, you can get rid of SOME of the phase jitter via the zero crossing detector route. The zero crossing detector provides an "average" function for the step just before the MSB changes and the step just after. This "average point" will sit much much closer to the right time regardless of MSB jitter as you increase filtering and increase the bits of precision in your DAC. Of course it seems it might be possible to seperately convert the lesser SBs as a "bias term" on the PLL output to correct for the jitters. Someone wanna analyze that one? (Hint - it's been done before.)

: > building HF QRP stuff or microprocessor/microcontroller projects?

In the USA, due to the FCC rules, the hardest stuff to build is
VHF gear. Getting spurs down 60 dB is much tougher than getting
them down 40 dB. Often, you need to add real shielding between
stages. On the other hand, you probably want to do that anyway
to keep pagers, cellular phones, TV, and FM broadcast stations
out of your circuitry.

On the other hand, depending on the technology you have available,
70 cm stuff can be even easier to build than HF gear. At 222 MHz
and above, no-tune etched filters are certainly practical for
those with expensive computer software. A set of boards for
432 through 5760 MHz is sold by Down East Microwave.

Steven,
What your attempting to do is admirable, however it would involve changing more than just the driver and final. You would have to increase the pre-drive stages to be able to supply enough rf to the driver. Also the power cable, on/off switch,and circuit traces are not designed to handle the current needed to opperate at 100-watts output. If you must have more output wattage I suggest you purchase an external amp or an RCI-2970 10-meter radio.

Thanks for all answers.
Here is what I thought before asking :

- Using a high Q tank.
- Using two varicaps
- Optimizing the input impedance for lowest noise (but how to compute Zin ?)
- Using a high frequency reference in the loop
- Using a TCXO as refrence crystal
- Divide the output of the VCO (I mean divide its frequency)

What would be the type of oscillator that would generate the less phase noise ?

Thanks and 73s.

Well, they don't show all the good stuff the Moto books show, like for instance S-parameters and whatnot, but MCM Electronics sells Japanese "2S" databooks for transistors, FETs, and diodes. I have only the bipolar transistor book. What you get is mostly in Japanese, but the data tables use the normal "hFE, Vce, etc." type symbols, so it's readable.

There's enough detail to allow substitutions. I can also pluck "2SC" transistors out of old junk radios and know what they're good for. The best part is all the currently available "2SC" parts are in one book - you don't have to find a book by a manufacturer that happens to make that particular part. I wish there was such a thing for "2N" parts!

Source record: 112149

Hiya, folks. I'm looking to build a QRP tranceiver for use on 40/80m CW (novice/tech bands). I've selected the KH6CP tribander described in the ARRL handbook because it's a self-sufficient tranceiver (I live in an apartment--this is a consideration) and because the notes mention that it's relatively easy to modify this tranceiver for other bands. Has anybody done this--preferrably for 40 and 80m? If so, would you be interested in sharing tips/instructions/TELLING ME HOW TO MAKE THE MODS (hint-hint ;-)) to build this?

Tnx es 73 de N0YVW SK

Isn't the usual case where the resistance is in series with the
reactive components? In this case, Q = X/R; larger X gives a
larger Q for a constant R. Of course, the R isn't constant,
it goes up linearly as the turns on the inductor increase, but
the inductance is proportional to the square of the turns; thus
a larger L is better for high Q. I'd also guess using a larger
L means that the smaller C required will also have a higher
Q...

>If large L's are used, the reactance goes up, the Q goes down, and
>the phase noise increases, per theory.

See above. I'd guess that parallel loading of tank circuits
isn't as much of a problem as the component series R.

>In the real world, there are other complications. For a given frequency

>finite range of inductance, so the designer is constrained from using an
>arbitrarily small value of inductance.

At upper UHF+, there are some neato ceramic resonators available,
but they're kind of exotic for home experimentation as far as I
can tell, since they have to be fabricated to the desired frequency.

Found -somewhere- on the internet. I forgot where however... 8P

-Cut Here-

Hello,

A few weeks ago I posted the following:

My friend is thinking about having a house built for him
and he was wondering if you all could offer some
suggestions in making his house "ham freindly". For
instance, having coax run in the walls to his shack or a
rotor mast port in the roof.

I wish to thank the following for their input:

Bob Smits, VE7EMD
Macy Hallock
Marv, KD4EGV
David GM4ZNX
Tom Bodoh
Gary Coffman KE4ZV
Mat Maessen N2NJZ
Scott Sminkey, WO1G

The following is a list of responses:

1. Run four pair twisted pair wire for all telephones, home run
to a central point for all jacks. Use Level 4 wire (less prone
to RFI and xtalk). You can use Shielded Twisted Pair, but it
shouldn't be necessary.

2. Run 2" PVC conduit from the roof, to the prospective
shack location. Stub the conduit thru the roof, using a
vent skirt, put a 180" elbow on the top. Do not glue on
the elbow, though. This run should have no more than
two 90" bends in it. Use 45" bends, if possible.

3. Prepare a support area on the roof structure for a roof
tripod, near the coduit stub. Even if you have use for
a tower, this is a good idea. Its hard to have too many places
to put an antenna.

4. Install Double Shielded RG-59 video cable for the TV runs.
Belden 8232 is a good choice.

5. Arrange for the phone company to install the network interface
inside the house, with the phone line completely buried and not

exposed on the side of the house. Better security and looks nice.

6. Prepare for a grounding system while the house is under construction.
Never, ever skimp on grounding....

7. If you have a basement, run conduit from the shack into the
basement. Useful for standby power (keep the 12v battery in
the basement) and control runs.

8. Wire in remote radion/ music speaker lines. Maybe even prewire some
control station stuff.
(Don't go for a cheap NuTone music/intercom. There are other solutions
that are decent...)

9. Get a professional grade security system installed.
(That's what F.M. Systems does, ask for advice when you are ready)

From: macy@fmsys.fmsystm.ncoast.org (Macy Hallock)

-

Here are my suggestions:

1. Coax or hardline in walls to antennas.
2. Separate subpanel for all electrical outlets in shack.
3. Additional telephone (multipair cable) pulled to shack.
4. Cable tv drop for shack.
5. Driven ground rod in shack area before concrete floor is poured.
6. Cabling installed in wall for rooftop weather station -even if the
station is added later.

Marv, KD4EGV

-

For what it's worth, here's what I did when I added a ham shack (closed
in a car port) last year.

Ran a 220 V feed to the new room, and installed a sub breaker panel.

Added electrical outlets everywhere I could concievably want them,
including a 220 outlet for a linear. About 8 of the outlets are switched
by a light switch near the door, to control desk lights, etc.

I prewired a number of telephone jacks - dual ones for the two phone
lines (for the voice and computer lines), at two locations - one at the
computer desk, one near the ham equipment for the phone and patch.
I also added four runs of RG-6 + extra cable through the wall for the
satellite reciever, plus extra shielded audio cables, so that I can feed
the stereo upstairs with satellite audio.

As far as the ham antenna cables go, I would not install the cables
within the wall, as the cables normally get replaced and/or changed
periodically. I made a plywood door in the ceiling of the shack, put coax

feedthrough connectors in it, and feed the cables to the outside between the rafters. The "door" is directly above the ham gear. (I figure on up to fifteen separate antenna feeds, all RG-8 or better)

All in all, I recommend adding extra electrical outlets wherever you could possibly want them. Having a separate sub-panel for the ham shack will also make it easier to switch in a backup generator, but make absolutely sure that if this is done, that there is absolutely no way of back energizing the power company's lines with the generator.

If you absolutely must install antenna cables in walls, use conduits, so that you can change them in the future. (Sooner or later, you'll want to.) Provide for antenna cable on every band you may wish to operate on, even if you don't install 'em right away. For me, for example, that makes a total of 4 VHF feedlines, 2 UHF, 8 HF and 2 spares. YMMV.

Plot it all out on paper, and do it several times. There's always something you forgot.

I read the reply about lots of circuits, 220v 110v, bench lamps off of a light switch by door with interest as it breaks my number one safety rule.

Should you ever have an accident, it is likely that the people who would have to try to save you will be unfamilier with your shack, and may never work out which circuit is biting you.

I feel happier in the vicinity of a large switch in a fully insulated plastic box in easy reach of someone entering the shack, with a bright red arrow and the words "safety switch" pointing to it, which kills all power in the shack.

It has never happened to me, so far, and I've designed power supplies as part of my job, BUT should it happen I want the dice loaded to favour me.

For multiple circuits, you'd need a set of ganged switches. It is also a good way to shut down without bothering to find everything that is turned on.

Hope you never need this,

Cheers
David GM4ZNX (everything is on 240v in this country)

-

I would also suggest ground fault interrupt protection...

The only problem with that is that stray RF currents may trigger the GFI syst
em.
Just simply following good grounding techniques should be enough.
--
Mat Maessen N2NJZ | maessm@rpi.edu
------------------------------ +----------------------------------

---
-

First things first, start with a good ground system. A Ufer ground system
should be installed in the poured footings, and radials should be pre-install
ed
from the tower pads. Ground window entrance bulkhead panels should be install
ed
where cable runs will enter the house. This should all be integrated with
the power and telephone ground system to prevent later ground loops. This
is really cheap during construction, and very hard to do right later.

You never pre-wire with enough cables, so conduits with pull ropes should
be installed to all critical areas so that additional cabling can be easily
added later. As a minimum, pre-install in the walls two 50 ohm ethernet/ham
cables and two 75 ohm CATV cables to plates in each room, Also pull multiple
telephone cables and enough power outlets. Don't daisy chain anything. Bring
all phone runs back to a distribution panel, and all CATV and ethernet runs
to other distribution panels. This will allow reconfiguration of the networks

at any future date. The radio room should have it's own cable closet with
conduits, punch blocks, and patch panels.

Use 6 inch walls rather than 4 inch. This will allow larger cable conduits,
and more insulation. For the radio room, there should be computer flooring
and Sonoguard sound treatment. A suspended room inside a room would be best,
but just the sound treatment will help. Shop air should be provided from a
central source, along with a central vacuum system to please the XYL. The
radio room should be on it's own power distribution subpanel, ideally with
full emergency backup and auto switching. Insure plenty of air flow. A
high volume, low velocity, air handling system is best. It will allow
equipment cooling without contributing noise. Avoid metal duct work, use
rigid foam panels for all ducts. This will prevent unwanted resonances

in the air system.

If the neighborhood zoning and covenants allow, freestanding towers are superior to house mounted antenna masts. If the zoning and covenants don't allow, consider building in a different location. Naturally, the higher the site the better for most ham operations. At least two, and preferrably three, six inch underground cable conduits should be installed from each tower base to the ground window. These should be fitted with non-rotting pull ropes and should terminate in weatherproof boxes. Route high level RF through one conduit, low level RF through another, and control wiring through the third.

All non-ham electrical equipment should be scrutinized for possible RFI generation. This includes light dimmers, HVAC controllers, security systems, major appliances, etc. For more ideas, consult the NAB Handbook.

Tom,

My wife and I had a house built about a year ago and I had a few ham things done that really worked out great. Here you go...

1. Consider where you might put a tower up, where coax from a dipole would fall to the ground, etc. Run buried 4-inch diameter PVC through the basement wall to that point. Use a combination of 22 1/2 or 45 degree bend sections on the outside end to take it out of the ground and bend it over so the opening is facing down (to keep rain out). A plug made of rotproof wood (I used scrap cedar decking material) with holes drilled in it for coax has kept mice from using the PVC to get into the house! This buried PVC has worked out really great to keep from having to string coax thru the air or lying on the lawn.

2. Run PVC inside one of your walls from your basement to your attic. This will give you an easy way to run feedline to any antennas in your attic down to where the radios are. Of course, you have to think about where the shack might be to pick the wall(s) you do this with. Even if you plan on a shack in some place other than the basement, run the PVC from basement to attic in case you change your mind later. If it's an upstairs room, you could attach a PVC tee section to bring it out into the room or just make a note about where the PVC is and punch a hole in the wall later to get at it. Note that having open PVC from basement to attic may be a code violation in some areas because it creates a raceway that can feed a fire. I use a PVC pipe like this to bring feedline from my discone scanner antenna down to the shack in the basement. I think the PVC pipe method is much better than simply

putting coax in the walls: you can choose coax type later and replace it at any time.

3. If you've selected a location for the ham shack, have extra wiring put it while you're building (much cheaper than doing it later). Go all out with this because the extra expense isn't much! Put in a 20 or 30 amp 240V outlet for the "big rig" you might get later. Put in a couple of good (20 amp) 120V circuits just for that room. Put the overhead light socket on a different circuit (probably one in common with other room), so if you blow a breaker, you'll still be able to see what you're doing! Think about using a subpanel in or just outside the romm with a master switch for safety purposes.

4. If you're thinking about a tower, now is the time to think hard! It will cost much less now than later to have heavy equipment dig the holes for the base and anchor footings and get the base and footings poured with whatever rods, pins, rebar frames, base, etc. you'll need. Just think: the equipment and ready-mix concrete trucks will be there already for the big part of the project (foundation, basement walls and floor), so tower stuff is peanuts in terms of extra time and materials. You will need to select a tower type and have a some idea about height to choose dimensions and materials like anchor rods and base plates. I planned for a Rohn 25G guyed installation of 50 to 70 feet.

5. If you're going with a basement shack like I did, drive in a ground rod or two where the room will be before the basement floor is poured, and voila, you've got a ground rod as close as possible to your rigs!

That's all I can think of right now...

Hello Chris and Ray,

I am currently working on a DDS would like to be able to connect the high order bit to the mixer through an LPF. I built a spread sheet based on the output from the high order bit and looked at the fourier spectrum generated. It looked ok in that there was no even harmonics and the odd harmonics were way down.

I'm using an IF of 10.7MHz with down conversion, ie dds operates above 10.7MHz

If I arrange for the front end to reduce images, is this a viable idea, or am I missing something here?

Best Regards,

Ian

Richard Karlquist (rkarlqu@scd.hp.com) wrote:

: a shield can. Use a large L/C ratio in your tank.

Huh?

When a parallel tank is loaded with a resistance, the Q is equal to
that resistance divided by the reactance of the L or C (it doesn't
matter which, since the two reactances are equal in magnitude at
resonance).

If large L's are used, the reactance goes up, the Q goes down, and
the phase noise increases, per theory.

In the real world, there are other complications. For a given frequency
of operation, high quality inductors can be fabricated over only a
finite range of inductance, so the designer is constrained from using an
arbitrarily small value of inductance.

Has anyone tried to interface the AA NOAA WEFAX board to JVFAX 7.0?
The "simple" opamp comparator circuit works very well for HF fax.
The 2206 based VCO that takes the NOAA siganl and then sends it to
opamp comparator works. Just not to well. I have the old multifax
system and was wondering if anybody had had any success interfacing
it to JVFAX 7.0. The old multifax system worked ok but the resolution
was never what I had wanted. The AA board has an 8bit adc with all 8
bits brought out the ouput connector. Parallel ports are rather tricky
to feed. I am thinking that I will need to change the noninverting
output buffer to an inverting buffer. Any thoughts?
The JVFAX program is wonderfull. Anyone who has ever had any interest
in fax hf or NOAA LEO weather sats ought to check it out.

Try HAMCOM30. A schematic is in the program's docs on how to build the interface. It is relatively simple (I am in process of building one---in fact the PCB is at this moment being etched in my bathroom!!) to build the interface. It is available, I believe, by FTP at oakland.edu (not quite sure of the name).

2746. Ignorant question about envelope detectors

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-06-30 00:00:00 UTC
From: misc200@csc.canterbury.ac.nz
Message-ID: <1995Jun30.150509@cantva>
Source record: 112153

Hola Everyone,

I'm fairly ignorant of electronics, but I have a question which you may
be able to answer.

It seems to me that a standard envelope detector as used in the
detection of an AM signal would perform better if the standard fixed value
capacitor was replaced by a circuit which had a capacitance which varied with
changes in frequency.

If a large valued capacitor is used in an ordinary envelope detector
lower frequency 'message' signals would be detected well as the discharge from
the capacitor would be roughly linear over the short period of time to the next
signal.

However, at higher 'message' signal frequencies the 'slope' of the
discharge from the capacitor would not be steep enough to ensure that the
voltage across the capacitor at the arrival of the next carrier peak the was
below that carrier peak.

Me thinks that most envelope detectors compromise by having a smaller
valued capacitor, which unfortunately are not so good for the lower freqency
'message' signals.

I of course claim ignorance, so if I'm completely and utterly wrong
then feel free to correct my ignorance.

So if I am right, do there exist any circuits out there, which use off
the shelf components, which may be used as a sought of frequency dependant
capacitor.

Also a friend of mine had an idea about using a 'dual detector' in an
AM receiver, the idea is to use a bridge rectifier of Germainium diodes instead
of the standard single diode. Me thinks it should improve the quality of
detection. Any thoughts or comments on this much appreciated.

Regards,

Stephen Simpson

In article <3sumvg$cnj@rcp6.elan.af.mil>,
Chris Spacone <spacone@qnet.com> wrote:
>You could try using one of the many linear voltage regulator chips
>available in the market.

Keep in mind most of the common three pin linear regulators have
about a 2 volt input-output differential; for the device to stay
in regulation, the input must be about 2V greater than the desired
output. For example, a 7812 really needs about 14V in to give a
regulated 12V output. If the input drops, so will the output.
The voltage drop also increases as the load increases; an HT
that works OK receiving may not transmit correctly.

Also, most of the common regulators aren't specified to the
kind of transient voltages that occur in the automotive electrical
system. In fact, for large input spikes or negative input
spikes the regulator may fail, often as a short circuit (I've
tried this at home).

There are regulators designed for the automotive environment;
the LM2941 is a nice 5V part from NatSemi which is specified
for negative and large positive input transients. Also, the
input-output differential is very low, something like 600mV
with a 1A load. The downside is the +5V fixed output.... but
there may be similar devices at higher or adjustable voltages
available now.

I'd probably use an LC filter followed by a fuse and a healthy
Zener on the order of 19V/5W, like a 1N5356A, to protect the
power supply if I was worried.

I'm looking for a crystal in the range of 8.08333.. to 8.1 MHz, preferably in a FT-243 holder, but other styles will do. This is to put my Heath lunchbox in the 145.50 -> 145.80 (misc. & experimental) part of the bandplan.

Let me know if you've got one to sell!

Look on QRZ web server at http://www.qrz.com

Under the FTP option go into the files section, then the morse. There
are several files here. The ones I'm familiar with that I think do
what you want is PROCW and CW104. It has been a year or two since I
played with them, but I think they will do what you want.

or if you have a CD go ahead and spring $25 for the CD and get lots of
shareware stuff.

I am in no way associated with QRZ, just a satisfied customer.

I want to put up a trapped wire for 80 - 10 meters. Space is a major problem. I own the house but the lot is small and the deed restrictions are large. I have no large trees to run a wire up to and the house is only about 23' tall at the peak.

The question I have is can I put the wire up with a minimum ground clearance of 15' and use it as a modified sloping inverted vee with out too many problems? I want to tie to the chimney and the top ot the garage in one direction and the chimney and a elevated swallow house pole on the other leg. This will give me about 60 degrees of seperation with the 'point' of the vee pointed upward to the east and the other two legs pointing nortwest and southwest.

Will the wire be omnidirectional in this configuration or directional? I am a neopyhte at this and really need a little help. I am studing to take the ham tests and getting my 'shack' in order for the day when the ticket finally comes in.

Thanks for the help in advance.

Sequencers. When you key the mic it switches the preamp out, then the transverter (if you are using one) then keys the rig. Unkey the mike and it all happens in reverse. Works great, most of the time.

QST published an article on using the LM2941T adjustable
regulator in November 1989. It even has information
about the auto electrical enviroment.

They have one well known problem--you need a good electrolytic
or tantalum capacitor of sufficiently large capacitance and low
series resistance on the output of the device to keep it
from oscillating. The more current you draw, the smaller
the capacitor you need. A 22 uF tantalum works well in many
cases, though I'd recommend you look up the data book notes
or copy a circuit that works.

Let me clarify this. Use a large inductor and small capacitor, but
tap way down on the tank to avoid de-Qing it with the resistance.
Yes, there is a limit to how high you can go (due to self resonant
frequency getting too low), but, generally, higher values of L result
in higher values of Q, other things being equal.

I'm bazck...

Well. Okay for using a large L with a small C.
But what about capacitive leakage ? Stray capacitance ?
What about the Q of the varicaps ?

There is something I don't really figure out :
Which one of these hypothesis is wrong :
1. A small C implemented with a varicap will be more sensitive to thermal or other types of noise, thereby increasing phase noise of the VCO.
2. Since small changes in varicap command signal produce great swing, the PLL will reduce more efficently the noise.

Thanks.

Rick is absolutely correct.

At low power levels, 1/2 dB of loss isn't much. But it's 122 watts if you're running a KW. Nobody'll notice the loss in your signal, but you'll sure notice it if you grab a core dissipating that kind of power.

The folks designing broad-band transformers for high power have a tough job, because with reactance comes resonance. Resistive impedances are much easier to live with over a wide frequency range.

My apology for looking at the problem from my narrow perspective, and thanks to Rick for bringing the other viewpoint to light.

(I'm assuming you're referring to a VFO rather than a crystal oscillator,
although I suspect my comments apply also to crystal oscillators.)

Hm, this is interesting, and a bit of lore I hadn't heard before. In the
oscillators I've designed, the active element wasn't a noticeable contributor
to temperature sensitivity, although I'm sure it would have shown up sooner
or later if I had tweaked the passive components extremely carefully. In
a well-designed oscillator, you shouldn't be able to detect the temperature
sensitivity of the active device, unless you've managed to compensate the
passive components (particularly the inductor) to an extraordinary degree.

FETs are fine for this use.

I haven't tried it, but according to the SuperMorse manual, SuperMorse
can send Morse code using one of the RS-232 support lines, like DSR (DTR?)
driving a transistor switch to key the transmitter. If a transistor is
not compatible with the transmitter keying circuit, a relay can be driven
by the transistor. The relay then drives the transmitter CW keying input.

Lewis:

What you describe will certainly not be optimum, however, it should work. There may be some directivity on some frequencies, but I wouldn't count on it. You may have to tinker with the
wire segment lengths some to maintain resonance, but that's what ham radio is all about anyway.

With the proximity to house wiring that you will have, you may experience some mutual interference to/from TV and telephone service. This may require some extra effort to overcome
or may necessitate avoiding some freqencies. You will just have to wait and see.

If it's any consolation (I'm almost ashamed to say this), I have two acres and no deed restrictions but because my interest is mainly 2M CW/SSB, my HF antenna is a trapped dual-band
20/80 meter dipole 20ft high in the middle and about 10' at the ends.

With 100 W on 80 meters, I can work all of the US and have worked JA, VK, etc so don't dispair. Just stay out of contests :-)

Best wishes in your studies and many happy years of hamming.

Regards, Wes Stewart, N7WS

I agree that the active device should drop out of the picture in an
optimum oscillator. I don't know to what extent this is possible, or
to what extent the original poster had achieved it. I guess he could
apply circuit cooler to his JFET and see what the damage was. Another
test is to vary the power supply voltage or bias current and note the
effect on frequency.

I was specifically complaining about JFET's not FET's in general. A
UHF dual gate MOSFET like the BF98X/BF99X series would probably be fine.
An old war horse like the 2N4416 has rather low gain and high capacitance.
Lots of Miller effect to act as a reactance modulator across the tank.
I suspect the original poster may have been using something like that.

Speaking of crystal oscillators, here is an anecdote. In the early 1970's,
a company (Konel) where I worked that made marine radios happened to have
an engineer who fell in love with FET's for some reason. He started using
them everywhere, whether it made sense or not. One place they showed up
was the crystal oscillator in the HF SSB radio. The oscillators drifted
like crazy for the first minute or so they were turned on as the FET junction
temperature increased. So everytime you went from transmit to receive or
vice versa, your voice "unclarified". About this time, another engineer

at Konel left to go to a competitor and when he got there, he copied a bunch of our circuits including the above oscillator. We thought it served him right. Shortly thereafter we went back to bipolar oscillators and the problem went away.

Thanks for your comments.

From: sem2r@galen.med.Virginia.EDU
Message-ID: <DB21rr.Esz@murdoch.acc.Virginia.EDU>
Source record: 112076

I'm looking for the "male" portion of a Kenwood, standard eight
pin microphone connector. This is the portion which mounts in
the rig, rather than on the microphone cord. I want to make a
microphone switch box to change between different microphones,
and I haven't been able to locate a source for a male mic. connector
with this many pins. The radio shack versions only have 4
pins. The female 8 pin connectors are easy to find, but the
male 8-pin counterparts are hard to come by.

Anyone know of a good source??

BTW: I'm also looking for a source for the male 13 pin DIN
connector for one of the accessory jacks on the back of many
current Kenwood rigs.

Thanks!!

My 2 cents....
I used simple interlocking relays for about a year and lost 4 or 5 GASFETS. About $25 worth, not to mention the hassle of disassembling the array to replace.
Now I use the sequencer from the Handbook. Premade boards are availible for about $6. Works fine. Haven't lost a transitor in almost two years.

: What is the effect of its phase noise on the phase noise output of the DDS ?
: It seems to me that there must be some.
: But I may be wrong.

: Vince, F5RCS/I2

Yes, there will be. Although I'm not able to do the analysis
myself, I know for certain that the DDS will not improve upon
the phase noise of the XTAL reference. My immediate impression
would be that the DDS phase noise would be that of the XTAL
plus added noise from the DDS itself.

This is a very intersting question. Can anyone shed some light
here? It doesn't appear to be as simple as the phase noise from
a PLL, which can be done graphically.

cingersn@bdam.win.net (Carleton C. Ingerson) writes:

>
>Can anyone out there in Cyberspace furnish me with the measurements
>for a multi-band folded dipole antenna?
>

By definition, there is no such thing. A dipole is simply an antenna with two poles, usually fed at the centre with ladder line, twin lead or coaxial cable. The approximate dimensions for such an antenna can be determined by the formula 468/f (MHz), which will give you the length in feet of the entire antenna.

A folded dipole begins with a dipole antenna, but an extra element is then connected not to the feed line but from one end of the antenna to the other, somewhat like this:

```
_____________________________________________________________
|_____________________________ _____________________________| |
| |
| |
| |
| |
```

Antennas of this type are often constructed to raise the feedpoint impedance of the antenna, since the impedance is about four times the impedance of the simple dipole.

>I would like to construct one similar to the crude diagram below:
>
```
>oo-----------------------------------------------------oo----
> \ /
> \-----------------------------------/
```
>
>As I said, this a crude diagram showing one side of the antenna.
>
>Any assistance will be greatly appreciated.

I think what you want is not a folded dipole, but a multiband dipole, which can be made quite easily by adding more than one pair of elements to the same, common feedpoint.

A typical antenna might include an eighty metre dipole, a forty metre dipole, and a twenty metre dipole, all made approximately to the 468/f formula, and usually connected to a 50 ohm coaxial cable without a balun. The dipole elements can be strung at right angles to each other as dipoles or inverted vees, or the ends of the elements can be separated by 5-10

feet to minimize the interaction.

You will find some adjustment is necessary.

Sorry, I forgot about the name and callsign when signing up for the QRP list; in the past, you just used command SUBSCRIBE QRP-L, but now they are on a different host, using ListProc instead of majordomo. Under majordomo you could send a command to get a listing of all subscribers to a mailing list, and it returned a list of e-mail address--not too helpful, as a large number of those are quite cryptic. When you sign up for a mailer under ListProc you are supposed to include name and call sign. That's your real name, not e-mail address--it strips that off the header so you don't need to repeat it.

To get a list of all the people on the list, send e-mail to

listserv@lehigh.edu

and in the text write

RECIPIENTS QRP-L [not case sensitive, but I used upper case
to make it plain that it's QRP-L, not QRP-1.]

You will shortly receive an automated reply with e-mail addresses along with the corresponding names and call signs--that's why you're requested to use them when subscribing. It makes it soooo much easier to find out who is really on the list.

Again, for the latecomers, to subscribe to the QRP mailing list, send e-mail to

listserv@lehigh.edu

and in the text say

SUBSCRIBE QRP-L [your name] [your call sign]

I'm looking for a used HF transceiver along with related
equipment. Essential specs include:

1. Ham bands, *and* general coverage
2. Solid state construction
3. Digital readout/s
4. Computer interface
5. Memories

Options that I am looking for are:
6. Antenna tuner (internal or external)
7. Power supply (internal or external)
8. 110/220 volt operation
9. Microphone
10. Manuals/Operating Instructions
11. Any other accessories/equipment

If a direct shipment to my home address in Canada is not possible, I
am prepared to pick it up at the Pigeon River (near Duluth, Minn)
border crossing.

Please contact me either on this conference, or by voice/fax at:
807-768-1491, all day and evenings, EDST.

Thanks

>Yes, there is a limit to how high you can go (due to self resonant
>frequency getting too low), but, generally, higher values of L result
>in higher values of Q, other things being equal.

This can be confusing. *Component* Q is X/R, with R being the *series*
resistance of the component, so the higher the value of X, or lower value
of R, the higher the Q. The parallel tank *loaded* Q, however, is R/X,
with R being the *parallel* loading resistance, so high values of R, or low
values of X, will give higher loaded Q. Both types of Q occur together
in real circuits.

Large inductances typically have a disproportionately larger series R than
small inductances, so smaller inductance values will often show higher
component Q. Capacitors typically have very high component Q, so a high C
LC tank will generally have the highest unloaded Q. Tapping down on the
tank inductor can make the parallel load R look much larger than it is
due to auto-transformer action. This, coupled with a small inductive X,
will result in a higher loaded Q.

High L tanks are generally undesirable because of the lower component
Q, and because of the very wide tuning change caused by a small change
in C. With PLL loops that use varactors, this means that a high L tank
will have much more phase jitter due to noise currents in the varactor

than would a high C tank where most of the C is supplied by a parallel fixed capacitor.

>Just curious (for informational purposes only).
>Thanks, mikkey.

You bet a spark transmitter can generate interference over a very
broad band of frequencies. However, receivers in the 800 MHz
area use FM, and are relatively immune to the AM noise generated
by a spark gap transmitter unless it is overpoweringly strong.

Since you have a space/height problem, just put up what you can and
use it. In many cases like yours, a good antenna tuner is a big
asset, it may allow you to load whatever form of antenna that you
can get into the air. I have found that low antennas can be somewhat
directional in unpredictable ways due to the close proximity of
surrounding objects. Put it up and see what you get, it will
certainly be better than nothing. Later you can try moving things
around to see if it might work better (or worse).

I personally use a 102 foot wire at about 25 feet strung from house
to tree to tree, it is painted with black, then green. then brown
paint to keep it from being obvious, and I feed it in the center
with ladder line just long enough to reach the tuner in the shack.
It's not the best, but it works, and the neighbors haven't called
in the covenant police yet.

In case you need a directional antenna for the low HF bands, first
get your antenna farm plot of ground (with no restrictions)
and go from there - the rest is easy by comparison.

GL & 73,
Don W3FPR

> value capacitor was replaced by a circuit which had a capacitance which
> varied with changes in frequency.

If you are talking about a TRF (direct detection - like a crystal set):

It really depends upon what you mean 'better'. If you are concerned about maintaining a maximum high frequency response after de-modulation then I think that you are right. However, normally the ratio of the modulation frequency to the carrier frequency is sufficiently great that the response of the envelope detector will not vary too much on carrier frequency.

In the case of a normal super-het design, the IF frequency is the same indepenant of signal frequency (sometimes around 455kHz) so the detector will behave the same.

Make any sense ?

There's a pretty good article in the December (November?) 1993 issue of QST on temperature compensation of VFOs, including a little temperature controlled chamber for testing. It concentrates primarily on choosing capacitors to offset inductance drift.

OK... I'm trying to rig up an AC adaptor for something. The specifications for the gear say that it needs 9V at 150mA. I've got various 9V Radio Shack adaptors lying around my shack, but they all have ratings greater than 150mA. I think the closest is 300mA, and they go up to a full amp.

Basic question.. Can I get away with using a larger amperage supply, or will this be a BAD THING? I really don't want to "let the smoke" out of my pocket computer, so keep in mind that it's electronic/computer stuff here.

My basic sense says that it should be fine, as long as the device is less than the supply, it'll be OK. However, a little knowledge is a dangerous thing, so I thought I'd ask.

The warning about household wiring was something I hadn't considered.
After reading your message, I have started to consider a different
location for the wire. I think I can get the center up about 20'-25' and
the ends about 12' by adding a couple of more bird houses in the back
yard. This would let me stretch it out above the back fence which is 72'
long. I'm going to try both for a couple of days and see which if any
will hear better. I'll be glad when the next exam day comes. I think I

have the written, now if the code will come.

If what ever you are using only requires 150ma, them that is all it is
going to ask for. The rest is just availible surplus capacity. Go for it!

Do keep in mind, however, that those "power cube" or "wallwart" units have no voltage regulation and often a high output impedance. Effect: the output voltage rises above the rated voltage as the load decreases. A unit rated for "9V" may have an open-circuit voltage of 12 to 14V, which decreases to about 9V as the load is increased to the rating. So using less than the full current capacity from one will mean more than the rated voltage. Units with higher current rating (e.g. 1A) also have less internal resistance and thus usually less variation in voltage with changing load. It may be a good idea to measure the open-circuit voltage before connecting and make sure that it is acceptable to the device. In your case, if the original supply was also an unregulated power cube, the computer is probably built to handle large variations in voltage.

2793. Pulling Freq. in 100 MHz Quartz Crystal Osc.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-02 00:00:00 UTC
From: Bob Mueller <IFF161@DJUKFA11.BITNET>
Message-ID: <95183.164128IFF161@DJUKFA11.BITNET>
Source record: 112102

To anyone with experience!
I need a pair of quartz crystal oscillators at about 100 Mhz with
their frequencies spaced by about 20 kHz. Is there a fair chance of pulling
one or both (in opposite directions!) so I can take two standard crystals
and reach this spacing. As a percentage it is not very much but I worry.
I assume the standard crystals are AT-cut running on the 5th overtone
(most likely choice), but I have the impression overtone crystals are not
very cooperative, one reason for sometimes running on an overtone at
frequencies as low as 5 MHz.
Thank you for any expert advice!

Simple question - sorry I could not find a FAQ that addressed this.

I want to erase EPROMs at home. I could spend $40 on an eraser
but I am looking for a cheap way out.
EPROMs typically need UV at 2537 angstroms with an integrated
dose of 40W/cm**2. Is there a consumer type of product (read cheap)
that is capable of this? I have seen UV(?) lamps for plants, will
this do it? How about sunlight? I don't really care if it takes a
day to erase the thing.

Thanks ahead of time for any help,
Bruce

Bob,
Overtone crystals operate at a harmonic of the crystal blank, as
you may already know. To keep them from operating at a different over-
tone (harmonic), we generally use an oscillator circuit that contains a
resonant LC tank circuit as well, such as a modified Pierce or a grounded-
base Colpitts.
The Colpitts is best suited for pulling the crystal, and is by
far the most popular when designing VCXOs (voltage-controlled crystal
oscillators). Marvin Frerking's book "Crystal Oscillator Design and
Temerature Compensation" is an excellent source of information on this
subject.

From: jackl@pinetree.microserve.com
Message-ID: <3t71o1$aum@nuclear.microserve.net>
Source record: 112106

Can someone tell me what the dimensions are for the space between the centers of the mounting slots for the following EIA panel heights:

5-1/4"
7"
8-3/4"
10-1/5"

There will only be two slots on each side of the panels. I want to cut these slots close to the upper and lower edges (say, within about 1-1/2") and they will be centered vertically on each side.

Information will be greatly appreciated.

73,

Jack WB3U

The one thing to watch out for here is that many of these "power bricks" have
poor voltage regulation. They might put out the correct voltage at the
rated current, but the output voltage will be significantly higher at a
lower voltage. The only way to know for sure is to put a load that will
draw the amount of current you want (a suitable resistor, for example) on
the supply, and measure with a voltmeter to see what you get.

If the output voltage is suitable, the larger supply should be just fine.

2799. wanted Test Anecdotes

I'm not absolutely sure this is the right group.
But it was recommended by a regular.
Presumably because it is full of friendly "hands on people"
who like details.

In my spare time, i'm co-writing a book on many aspects of
electronic/light electrical Production Test of products (not chips).

I'm currently looking for interesting/humourous/illuminating
anecdotes on how easy it can be to screw things up.
(or even a celebration of getting it right, although
I suspect these will be rare)

All reasonable and considered submissions will be acknowleged
in an appendix at the back of the book.
All Used submissions will be fully acknowleged, and at Least
one copy will will be posted to the provider.
(extra will depend on the final format of the book)
Any edits will be agreed beforehand (mention of specific
names etc. may require some masking, for a number of reasons)

Any pointers to your favourite sources/books on test would also
be appreciated.(Robert Pease excepted)
(not your reading lists..those you actually read)

Hmmm... if I remember correctly, direct sunlight (perfectly OK) takes
one to two WEEKS for a reliable erase. I went down to the local
hardware superstore and bought a 6" and an 8" flourescent lamps. Then
I dug through the yellow pages until I found a supplier of disinfectant
UV bulbs that fit the lamps. Then I turned them on and blinded myself
completely. OOOPS... OK, I knew that this UV could damage my eyes so
I took a suitable small box, lined it with aluminum foil and mounted
the erasure lamp inside. I then cut some foam strips to match and used
them to adjust the lamp to chip distance. To use the box, I mount the
chips, close the box tightly and place it out of the way where it won't
accidently shine in my eyes. Thirty minutes later erased chips by the
dozen. Admittedly, the bulbs are $20 to $30 each and the whole thing
cost me $60 to $70. But I now have a lifetime supply of erasers equal
to a couple of hundred dollars of commercial stuff and I still haven't
gone completely blind...

Richard,
Its ok to use a power supply with a higher current rating than your load requirement provided the voltage regulation is good enough to keep the voltage close to the same value.(so as not to exceed the breakdown voltage rating or the dissipation rating of any component in the load)
The 300 ma. supply will run cool with only a 150 ma.(50%) load.
Hope this will help,
Dallas Lloyd
lloyd@nando.net

: My 2 cents....
: I used simple interlocking relays for about a year and lost 4 or 5 GASFETS. About
: $25 worth, not to mention the hassle of disassembling the array to replace.
: Now I use the sequencer from the Handbook. Premade boards are availible
: for about $6. Works fine. Haven't lost a transitor in almost two years.
:

While I don't wish to decry the multi-step changeover sequencers (the ARRL Handbook design works FB) it can all be done with just two relays.

This circuit has worked reliably for over ten years, with key-controlled changeover of 1kW at 432MHz and NO GaAsFET preamp failures - ever! So if you want a regular excuse to try the latest new GaAsFET, maybe this circuit is not for you :-)

The basic circuit came from G4DGU, founder of the original muTek company. It works for me, and for several others too, so we included it in 'The VHF/UHF DX Book'.

What follows is the best I can manage within the limitations of this ASCII medium. If you draw your own circuit diagram from the details below, it should all make sense.

The whole idea of sequenced changeover is not about switching "fast enough" - it's all about switching SLOWLY enough.

There are two DPCO relays. RL1 is the 'slow' relay, slow to make and slow to break; and RL2 is the 'fast' relay. By interlocking slow and fast changeover contacts you get the following sequence of events.

RX to TX: fast changeover of coax relays
fast removal of RX 12V supply
delayed 12V supply to transverter/exciter
delayed PTT to PA

TX to RX: fast disconnection of PTT to PS
fast removal of tvtr/excr 12V supply
delayed release of coax relays
delayed 12V to RX

This gives time (a few hundred milliseconds) for all the
necessary changeovers to take place. It doesn't guarantee
that they HAVE taken place, but in practice it works reliably.

The VHF/UHF DX Book also contains a much more elaborate unit
which includes 'tell-back' from auxiliary contacts on the coax
relays, and uses the external ALC input to the transceiver
to hold off the RF drive until everything is ready to transmit.

This simpler circuit assumes that all coax relays are energized
on RECEIVE - which is strongly recommended because most failure
modes give protection to the preamp. It also protects the
preamp for the large proportion of the time when the whole
system is unpowered. If the masthead relay fails, it leaves
you with the antenna connected to the low-loss TX feedline,
so maybe you're not completely off the air.

```
-------------------- +12V DC
| |
R1 |
| |
RL1+C1+D1 RL2+D2
| |
D3------- D4
|
PTT(gnd) from exciter
```

RL1 and RL2 are both DPCO.
Each relay has a diode (1N4001 etc) in parallel,
cathode 'up' (towards +12V side).

RL1 has a 6V coil
R1 has same resistance as the coil of RL1

C1 = a few hundred uF in parallel with RL1 coil.
Select to make a few hundred milliseconds delay between
RL1 and RL2 (audible 'ker - lick' on both make and break).

D3, D4 = 1N4001 etc, cathodes 'down' (towards PTT side)

Relay contact wiring: (join X-X and Y-Y)

Centre Normally closed Normally open

RL1 c/o 1 +12V supply X +12V to exciter

RL2 c/o 1 X +12V to RX (no connection)
+12V to coax relays
(on RX only)

RL1 c/o 2 ground (no connection) Y

RL2 c/o 2 Y (no connection) PTT (gnd) to PA

That's the basic circuit. Mine is built into the transverter, which receives its PTT (ground) from the HF transceiver, and passes on a delayed PTT to the PA.

The coax relays and the masthead preamps are all fed from the same switched +12VDC, up the coax line between the transverter input and the preamp output.

With ordinary PTT-operated phone, it works fine - press the PTT, and by the time you've drawn a breath, it's ready for you to start talking. It doesn't work with VOX, because it misses the first syllable, and on CW it loses the first dot - but I know of no sequencer that does better. The important thing on CW is that it's always safe to hit the key, because the whole system will change-over reliably without blowing anything up.

An afterthought - maybe a large part of the reliability comes from not trying to achieve too fast a changeover. If you really try to shave the margins, the system becomes very vulnerable to a relay sticking for a few tens of milliseconds. That may happen only once every few months, but it may be just enough to throw everything out of sequence and kill the preamp... again.

Hope this may be useful to someone.

(Standard disclaimer: I'm not mentioning The VHF/UHF DX Book to try and sell more copies. It's simply the place where I and others have collected our best ideas on the subject, in a longer format than this ASCII medium allows.)

2803. Need ICOM R70 Service Manual & Filter Info

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-03 00:00:00 UTC
From: geoffs@onr.com
Message-ID: <3t981a$bdd@Sierra.onr.com>
Source record: 111972

I've posted this to several Usenet rec.radio.* groups, thanks for your patience if you've run into it previously.

I recently acquired a super clean R70 at a very attactive price. It's got a few shortcoming that I'd like to remedy.

First, I need the service manual with all of the alignment instructions, specs and schematics. I can probably buy one from ICOM but those things sometimes get left behind when an owner sells the hardware. I have the operators manual already.

Secondly, anyone got an FL-44 or FL-63 (I'd like both) for sale? Anyone know of a Fox-Tango equivalent?

Finally, there's a Murata 455kHz AM filter that's leagues ahead of the cheapie that's standard in the R70. It's called a CFU 455 I or CFU 455J. Murata stuff's hard to get these days. Anyone got a source or a spare one?

Thanks again.

Geoff Schecht NQ7A Austin, TX

I've erased them for years using a small germicidal fluorescent
bulb fit into a standard fixture (12" bulb). The only caution is that the
short wave uv is dangerous and can cause cataracts/eye damage with exposure.
I use my eraser under a metal baking dish. I paid about $15 for the bulb in
the late 70's and I'm still using the same bulb (probably about 100 erase
cycles later...). Not pretty, or particularly safe - but it works!

in kit form?

Yup. Most of the kits are accessories and QRP equipment, however. I
don't know of a major kit supplier that sells a line of full-power rigs
like Heath's.

You'll find Ten-Tec, MFJ, OHR, Small Wonders Labs, and other kit suppliers
advertised in major ham magazines. There are also many smaller
companies. (One of these is Wilderness Radio [415-494-3806] which sells
the NorCal 40A and Sierra CW transceiver kits that I originally developed
for the NorCal QRP Club.)

If you have more specific questions about kits, let me know.

Bob,
Its been a long time since I was an engineer with a crystal mfg. co., 1950's), but I think you may have a problem with stability of oscillation or frequency stability. I would go with crystals cut for the two freqs. required. You can get crystals cut to frequency reasonable from International Crystal Co. I don't have the address handy, but if you have trouble finding it let me know.

Good luck with your circuit,
Dallas Lloyd

I believe some component manufacturers are trying their best to
confuse use laymen. I had what I thought was a ceramic disk cap
which I used in a VFO - turned out the dang thing was an inductor.
Same shape and value markings that would lead one to believe it was
a cap.

I mentioned this error on the QRP email list and someone sent me a
bunch of caps and inductors disguised as 1/8 watt resistors!

: Chris: Please reread Frerking's book (or any other book on crystals)
: and learn that "overtone" is not a synonym for "harmonic", although
: it is easy to see why people would confuse them. Let's not confuse
: Bob a priori.

Yes, you're correct. Poor choice of words on my part.
I was trying to avoid getting sidetracked into a dis-
cussion of the resonant modes of a crystal blank. I
instead wanted to address the immediate problem.

: Having said that, unless you know exactly what you are doing, you
: probably won't be able to achieve +/- 10 kHz. (The first 100 MHz
: VCXO I built 20 years ago pulled +/- 100 Hz.!, and I'm not sure
: even now I could get 10 kHz. out of a 5th overtone.)

A modification of Frerking's grounded base Colpitts circuit
gives far more pulling. Use a series-resonant crystal and
use it in place of the base bypass capacitor. In the tank
circuit, replace the crystal with a coupling cap, and then
adjust the tank circuit for pulling. In a VCXO, the lower
capacitor in the tank becomes the varactor. I have a 125 MHz
VCXO at work that is <VERY> tunable.

: Another approach would be to use 50 MHz. 3rd overtone xtals with the
: oscillators followed by frequency doublers made out of SBL-1 mixers.
: Still questionable to save $30.

Yet another possibility would be to make a single, good
100 MHz crystal oscillator, then mix it with 10 KHz using
the same SBL-1 mixer. You'll get some 100 MHz leakage,
but you'll have two tones 20 KHz apart. Does this help
you any??

We keep making it better, not more expensive!

: that is capable of this? I have seen UV(?) lamps for plants, will
: this do it? How about sunlight? I don't really care if it takes a
: day to erase the thing.

Bruce... the UV light energy needed for erasing EPROMs exactly matches one of the strongest emision lines of the mercury vapor spectra. The erasing devices available on the market use mercury vapor lamps for that reason.

Some years back I found that mercury vapor germacidal lamps also work very well. The ones I have were made by GE and Sylvania (discontinued), are about the size of auto turn signal/tail light bulbs and will work just fine on 115 VAC with a 40 W light bulb in series. I had to hunt for these and when I finally found some... bought all the store had. As it turned out... the first one is still going strong and the spares were never needed. The plant GROW-LIGHTS won't work any better than ordinary flourecent lights... they just drop a bit here and there. Sunlight could work... think in terms of days... weather permitting.

I can erase up to five EPROMs in one 15 minute cycle by putting a square cardboard sleeve over the bulb (one hole on each face) holding them on with a rubber band, the last one goes on top. You need to be aware that the UV light can zap your eyes (actually it's like getting a sunburn on the inside of the eyeball). I flip the switch and walk out of the room never looking directly at the bulb.

Since I have never needed all the spares... would be happy to let them go for a reasonable sum. Far, far less than you would pay for a ready made unit. If you or anyone else is interested, email.

TV>I dug through the yellow pages until I found a supplier of disinfectant
>UV bulbs that fit the lamps. Then I turned them on and blinded myself
>completely. OOOPS... OK, I knew that this UV could damage my eyes so

TV>Admittedly, the bulbs are $20 to $30 each and the whole thing
>cost me $60 to $70.

A simpler place to get the "germicidal" bulbs is your local aquarium store. Tell them you need a replacement 4w bulb for your "Sterilizer" (tell them Hawiian Marine if they ask for a model). The bulb is about $20. You'll then need a ballast, some sockets, and an enclosure. It'll probably cost you $40 to make a home brew eraser, so why not just buy a finished one for that price, if you know of one? There really is no cheap way out due to the lamp price.

I built one, as Ted did. I had an old Sterilizer from a fish tank. I just disassembled everything (I had ballast, sockets, bulb from sterilizer) and built it into a box.

And as Ted Viens says, the emissions from this lamp are "deadly" to your eyes. DO NOT UNDER ANY CIRCUMSTANCES LOOK AT THIS LAMP WHEN IT"S ON!!! I once had a UV exposure burn to my eyes from reflected short wave light. It is not something you want to experience, it is very painful. I'm quite sure that enough exposure could permanently damage your retina or blind you. Also avoid skin exposure to the lamp, it does cause "sunburn" QUICKLY.

Far more than +/- 100 Hz. or far more than +/- 10 kHz.? Anyway,
how much do you get? The last 125 MHz VCXO I designed was good for
+/- 5 kHz. at best, although I wasn't trying for +/- 10 kHz.

My experience (and it is extensive) is exactly the opposite, at least
for inductors wound on ferrite or powdered iron toroids. As you add
turns, the Q goes up, even though you have to make the wire smaller
to do so. I don't know why this is the case, because using twice as many turns
of wire of half the diameter should quadruple both the inductance and
the RF resistance, but in reality, the RF resistance doesn't quadruple,
at least as indicated by the Q. Maybe the proximity effect gets into the act.

For air core inductors at VHF, it is also hard to get good Q at low
inductance values. The Q of a 4 turn coil is always better than the
Q of a straight piece of wire, or even a strap, in my experience.

>High L tanks are generally undesirable because of the lower component
>Q, and because of the very wide tuning change caused by a small change
>in C. With PLL loops that use varactors, this means that a high L tank
>will have much more phase jitter due to noise currents in the varactor
>than would a high C tank where most of the C is supplied by a parallel
>fixed capacitor.

With a high L, small C tank, you can use a low capacitance tuning diode
and you won't have any more tuning sensitivity (MHz/volt) than you
would with a lower L, higher C tank. You can put several coils in
parallel to get the equivalent of a lower inductance (but with the
Q of a higher inductance). One design here at HP uses 96 inductors in
parallel. Somewhat extreme, but the circuit does kick butt (they
do know what they're doing at the Spokane division).

The limiting factor with high L/C tanks, as I said in a previous post,
is the self resonant frequency problem of the coil. Note that using
multiple coils in series to raise the SRF solves that problem but
doesn't solve the Q problem.

Hi Anton, 170 Hz, 50 baud doesn't sound like a description of Morse code.
Sounds more like Frequency Shift Keying and a Morse code decoder will not
decode FSK. As a matter of interest, has anybody ever heard the term
"baud" used with Morse code?

: Sr. Engineer amprnet: kd4ghg@gate.n9gsa.ampr.org
: Process Systems Inc. ax25: KD4GHG@W4BS.#WESTN.TN.USA.NOAM
: --

It's simple:

1 Invert the TxD stream with a NOT gate.
2 connect the NOT output to the J & K input of a FF (74ls73). The CLK signal must be the TxC line in the 7201 (leading edge triggered?, if not, another inverter is needed), and Voila!! You get the NRZI in the Q output of the FF.

To receive the NRZI code a DPLL is needed, but it is not too difficult to design. A simple aproach can be:

- Use a CLK signal that is 16 times the baud rate, and feed it into a 4 bit binary counter (74ls93)
- Detect the transitions in the NRZI data with a D type FF conected to the 16X CLK and a eXclusive NOR gate between D & Q. Reset the counter to zero if a data thansition is found.
- In the Q4 output of the binary counter you get the RxC signal (Leading edge). Use this clock signal to store 2 bits of the NRZI data in a 2 D type FF's, then compare it with a XNOR gate. If the two bits differ you get a LOW.

(This Kind of DPLL was software emulated (assembler) and worked well for 1200 bps)

I hope you can draw an schematic with this ascii description :)

Make sure the polarity is correct. Make sure that the voltage
matches up. Excess current is no bigdeal as long as some mishap doesn't
cause you to use it :)
You are most likely using a DC supply. You could pop in a fuse,
or better yet, get a 12 volt cube, and run it into a little 7809 voltage
regulator, and you are set for safety. 12 volts in, and REGULATED 9
volts out. Pop a cap in parallell for ripple rejection, and you have a
power cube that is of higher quality than you would have if you baught
the factory original. ... and all this for less than 5 to 7 dollars

Well, I used a simulated 8 bit phase accumulator and took 256 and 1024
samples for the fourier analysis. Both specrums indicated no even
harmonics and low odd harmonics not dissimlar to the response
you would expect from a square wave.

If there is any phase noise it's not showing up in the spectrum. But
who cares anyway - I would like to use the output directly, not to
phase lock a PLL.

If it to introduces some noise into the receiver that's ok, as long as it is not substantial. I'm trying to build a continuous tuning receiver for 1-30MHz using frequency synthesis of some sort with an IF of 10.7MHz based around an MC3362 narrow band FM receiver chip. FM demodulation is built in! For AM I can tap off the 455KHz filter while for SSB, change the second LO to 10.7MHz and tap off the 10.7MHz filter through an LPF. (Well, ok it is actually a DSB receiver).

But there it is, a low cost AM/FM/SSB receiver for 1-30MHz.

Anyway I'm hoping I haven't made some obvious blunder here with respect to the DDS. What do people think?

Regards, Ian

2824. Help with tranciever for 2400 BPS modem

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-03 00:00:00 UTC
From: site@flood.xnet.com
Message-ID: <3t7lnc$92g@flood.xnet.com>
Source record: 112115

My previous post must not have made it through. (were having trouble with the server or some provider somewhere) My question relates to transievers, I am new to radio and need some direction. I am currently building two 2600 BPS modems (using the EXAR chipset XR-2400 with XR-2443 microcontroller) These are standard telco modems, but I am adding audio in and out jacks. Can I connect these directly to audio in/out of the transiever? If I used a 9600/14.4/28.8 modem could I connect it directly? What frequency should I look for? What price should I expect to pay? I am building 2 to set up a communications link between two devices through standard serial ports. I have heard *some*thing about a TNC, is this for packet radio? With my setup will I be able to access packet radio? Ack, I am confused. Will this require an FCC license, if so where can I get a book to study for it. I need a reange of a few miles, but if price is too much I can settle for around 500ft. Are there any FCC regulations against encrypting my signal? Can I keep it up for extendad periods?

That's enough questions, I would really appreciate it if you could Email me at site@xnet.com, thanks!

>subject.
>

Chris: Please reread Frerking's book (or any other book on crystals)
and learn that "overtone" is not a synonym for "harmonic", although
it is easy to see why people would confuse them. Let's not confuse
Bob a priori.

Bob: Pullability is inversely proportional to overtone number.
Fundamental crystals can be reliably pulled about +/- 1000 to 5000 ppm,
depending on a number of factors. Hence 5th overtone crystals can be pulled at most
+/- 200 ppm, which would be +/- 20 kHz. at 100 MHz. You might try
pulling one crystal high and the other one low, so that each is
only pulled 10 kHz. (but in opposite directions).

Having said that, unless you know exactly what you are doing, you
probably won't be able to achieve +/- 10 kHz. (The first 100 MHz
VCXO I built 20 years ago pulled +/- 100 Hz.!, and I'm not sure
even now I could get 10 kHz. out of a 5th overtone.) Unless
you just want to try to prove you can do it, you are probably better off
buying a pair of crystals spaced 20 kHz. apart for $15 each. Or

if the tolerance on the standard ones is poor enough, you may be able to select 2 that are that far apart in frequency.

Another approach would be to use 50 MHz. 3rd overtone xtals with the oscillators followed by frequency doublers made out of SBL-1 mixers. Still questionable to save $30.

RR>First of all, get rid of the JFET. A bipolar is typically much
RR>more temperature stable in the first place.

Sorry, wrong answer or certainly not the entire one. Using IC temperature
compensation techniques with an integrated bipolar array (CA3127 or
similar) can indeed minimize the changes in Ic vs temp and therefore yield
a stabilized gm. Problem is, gain changes have a smaller effect on
stability than things like loading of the resonant circuit and temperature
induced reactive element drifts.

JFETs like the 2N4416 or 2N5386 are commonly used in oscillators due
to their higher-than-bipolar input impedances and their very low S21
parameters. Gm is lower than in bipolars, though (as a rule).

72 Bob WB0POQ

Oxley in England made the "tempatrimmer" years ago. I don't think that they're still available bit you can gin something up that uses a +X TC capacitor in series with a -X TC cap that Rick mentioned. You wouldn't want to use a P150 with an N1500; you'd want an N150 or things would get fussy in spots.

Probably the best thing to do is stick the uncompensated oscillator, well buffered into a freq cntr, into an oven with a thermocouple and go through the old point-by point method of plotting temp vs freq on graph paper. Then find a cap arrangement that produces the complimentary temp characteristic and substitute it in the original ckt. <Remembering of course that the resonant frq is proportional to 1/(sqrt(c))>

2831. Motorola - tech help - where from?????

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-04 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Jul4.081421.57074@ucl.ac.uk>
Source record: 111990

I've got a problem trying to use an MRF-136 (15W VHF power FET). Its claimed to have 1dB noise figure, but the test circuit given looks (to me) unlikely to give this, as they use a low value (17 Ohms I think) stabilising resistor from gate to earth. If you simulate it (using small signal S parameters) without the resistor it makes a nice oscillator - not what I'm after. I want a very high dynamic range amp (1dB NF, > +40 dBm IP3) amp at 82 MHz, with about 10dB of gain.

If you work out the input Z at 82 MHz, you can see 17 Ohms will incur >1dB loss, so unless the device has a negative noise figure (thats a nice thought), I cant see how it can achieve it.

Can anyone either suggest how I might go about achieving this or suggest where in Motorola I can get someone who

(a) Can be bothered to answer tech questions.
(b) Knows what they are talking about.

So far, I've only tried the UK for help. The only person whose job it seems to be to answer tech questions from a University, is to say the least getting me *******. He first tells me the circuit will do it, then admits he does not know. Finally I get him to agree to ask an RF engineer, but some 3-4 weeks later I have no response.

Am I the only one who has this problem with Motorola?

2832. Low Dropout Current Regulators

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-04 00:00:00 UTC
From: zlau@mgate.arrl.org
Message-ID: <3tblm0$hmg@mgate.arrl.org>
Source record: 111991

Anyone have experience using chips like the LT1086 and LM2941T
below their low dropout voltages to take advantage of their current
limiting capabilities?

For instance, expensive power FETS can will burn up if you
have a stiff drain to source voltage and the negative bias
supply fails. But, if you limit the current, you can protect
the device. Modern regulators seem like an ideal
instead of an expensive FET blowing up, the regulator
just gets hot.

Question is, what about running a 12 volt regulator off
an 11 volt supply? Seems to work OK, I still get 10 volts
of output at full current (about 1 amp). You might consider
this to be one of those engineering tradeoffs--I still want
it to work when my batteries run low, but I'm willing to
put up with slightly degraded performance. After all,
people run amplifiers on the crowded HF bands without
stiff plate supplies....

This technique may even make sense for HF QRP rigs--a cheap
way to protect the final from low impedance loads. The
voltage regulator can protect against mishaps like automotive
electrical system burps and unregulated solar panel voltage.

Anyone have any trouble with regulator stability or ???

Go over to rec.radio.broadcasting and buy one of the used 10,000-25,000
watt transmitters that ocassionally gets posted on there. Then get a
dummy load capable of disipating the output power of your new
transmitter. Cost: $15,000 or so (excluding your monthly electric bill).

Kevin,

Just about any TNC made today (unless specified for the commodore, etc.)
will work with an xt. If you get a baycomm modem, you will need the
special software. Just about all the other TNC's out there will work just
fine with about any terminal program such as PROCOMM. Remember, all you
need is RS-232 on the PC and TNC, and a terminal program, and you're set.

Ken

Hi Rick,
This touches on a long standing question regarding loaded tank Q for
me. I get the part about the Z of the tank with a parallel load being
approx = to the load and Q=R/X, thereby to get a higher Q, use a big cap
and a small coil. However, an UNloaded tank is Q=X/R, R in this case

being the RF losses the coil and to a lesser extent in the cap, thereby for high Q use a big coil and a small cap.
Now take the high Q tank, ie, big coil, small cap and tap a load into it. (light coupling). The Q (now a loaded Q) goes down. To boost the Q up, would one use yet a larger coil, with a matching lower value cap, thereby raising the effective UNloaded Q of the tank, and in effect decreasing the effect of the loading? Or would one swtch to using a smaller coil and bigger cap in accordance with the Q=R/X formula above?
Another way to put this question I suppose would be, at what degree of loading does one put aside the formula for an UNloaded tank, ie, Q=X/R, and use the loaded formula Q=R/X?
Hope all this makes some sense!
Tnx es 72 WB0POQ

I am looking for software that will allow a 8-bit Soundblaster card to function as a crude oscilloscope. I was told by a fellow ham that a UK magazine (Wireless or Shortwave?) had a short review of it about 2 yrs ago. I can FTP or search via Archie or Veronica if someone can provide me with a filename.

I'd like to get a hold of it before my foray in 9600 baud packet, so I can monitor my deviation.

Please EMail if possible.

Thanks...

Maybe selected wide-tolerance "microprocessor" crystals could be used. Generally avaialable up to 50 MHz, so doubler or tripler would be required, although the new Mouser catalog lists a 96 MHz series resonant crystal. These often have tolerances of +- 100 ppm, so two carefully selected outlier ones could be different by 20 KHz before you started pulling. The original post did not mention anyting about the application: is it more important to have one exactly 100 MHz, or more important that the difference always be 20 KHz. Making one voltage-tunable, mixing the two together, then using a PLL to lock the beat frequency to 20 KHz could help a lot with the latter. If low phase noise isn't required, using VCOs for both in conventional PLL circuits is certainly possible, though more complicated than crystal oscillators.

: Far more than +/- 100 Hz. or far more than +/- 10 kHz.? Anyway,
: how much do you get? The last 125 MHz VCXO I designed was good for
: +/- 5 kHz. at best, although I wasn't trying for +/- 10 kHz.

I found out this evening that the pulling of a crystal is
inversly proportional to the SQUARE of the overtone number.
Therefore, a +/- 200ppm crystal in fifth overtone would
only pull +/- 4ppm (about +/- 500 Hz).

I don't recall how much my circuit pulled, but I do recall
that the amount did surprise me. I'll have to go back and
check that out (it has been a while). I was using a BBY40
varactor, which I'm told is by far one of the best, if not
the best, varactor for this application. Very linear, as
well.

Also, the other resonant modes for a 100 MHz AT-cut crystal
would be 20 MHz and 33 MHz. Since the original poster was
experiencing a low-frequency mode, he was probably using an
SC-cut crystal. The SC also has an interesting mode at 110%
of fo which can be used as a linear thermometer. This mode
is usually supressed.

Most of this information comes by way of a fellow I know here
who has worked for a number of crystal oscillator companies
over the years. I once got an interview with CTS Knights about
three years ago by way of him. Fascinating place! About 75%
of the building is a lapidary shop, as they cut their own
blanks from raw quartz crystal bars.

> convert this to Non-Return-to-Zero-Inverted (transition=space, no
> transition=mark)? Anybody with a SCC card schematic?

Feature for feature, the 7201 would come closer to the Z80SIO than
the Z8530.

The z8530 SCC is very popular for packet users because it does HDLC
with NRZI encoding, and has a DPLL for receive clock recovery.
One minor disadvantage the 8530 has is it requires an external divide
by 32 counter for the transmit clock. A schematic of a SCC card will
not help you.

To Interface the 7201 you will require an external NRZ to NRZI converter
for TX (D Type Flip Flop and Ex-Or gate) and a NRZI to NRZ converter
with clock recovery on receive. The best sources for this info are
the schematics of the TNC-2, which is based on the Z80 SIO chip.

I also understand the XEROX 820 used by the early packet pioneers
was based on the Z80SIO, and there is an external circuit make it
do NRZI

A simple external clock recovery circuit is prone to get triggered by
noisy data, but under most conditions, it is not noticable.

Hope this helps,
73

Hi all,
Just a note to all regarding this article in QST. While it is well

done, the folks at the mag messed up the graphs and some of the specs. As I recall the graphs are all off by a factor of 10 as is some of the Hz/Degree drift factors. This is pretty obvious if you read it carefully.

Hi R.T.,
Yes the current rating of the supply can be = to or higher than the
current required by the device. HOWEVER... be advised that these little
"wall wart" types of power supplies typically have very poor voltage
regulation along with poor hum filtering. This is not a problem for many
uses, but can spell real trouble for others. As it looks like you will
be running a device that may take this into account, I think you will be
ok on these counts, but it would'nt hurt to check your manual etc.
See ya. Bob WB0POQ

: mitter would effectivly jam the police's radar. (Informational Purposes only)

Quite unlikely. Police radar undoubtedly uses waveguide, which acts as
an excellent low pass filter. Microwave ovens operate at roughly 2.45
GHz, while the police use 10.5 and 24 GHz (approximately).

Anyone attempting to install such a transmitter is advised to conduct
tests in a location where the inability to control the vehicle won't
bother other people. See the Sept. 1994 QST about what the auto makers
say about installing transmitters in your car.

Source record: 112011

Joanne Dow (jdow@BIX.com) wrote:

: You are both "almost" correct here. A simple PLL can only filter out the higher
: frequency components of the MSB noise. If you have a relatively narrow band
: tracking filter on the signal going into the PLL, however, you can get rid of
: SOME of the phase jitter via the zero crossing detector route.

The PLL acts as a bandpass "tracking" filter itself.

The information in the phase register of a DDS is exactly perfect, the phase values it has to be able to represent are precisely within its resolution. The fun comes when we want to create smooth sinusoids up to a decent fraction of the clock frequency. One way of looking at the sine look-up table, DAC and filter is as a particularly neat interpolator.

In real life DDS's, the phase word is truncated (LSBs dropped) to keep the table size acceptable. After sine conversion, it would take an infinite number of bits to give absolute precision, even though the phase generator is precise AND finite. So, there is a second truncation forced by available and affordable DACs. Normally the DAC limitation is in the driving seat, and the truncated phase word is made 2 or 3 bits larger than the DAC word.

To get a quick mental picture of the nature of the unwanted stuff coming out of a DDS, think of the output voltage of the DAC as being a series of steps following the wanted sinewave. You can think of this as being the sum of the wanted waveform, and a "quantisation" waveform. The sinusoid has a simple spectrum, but the quantisation waveform is wierd shaped being odd segmented chunks of offset bits of sinewave. It will be different for different output frequencies, and will have a complex spectrum, sometimes containing components right down to the increment frequency itself.

As Joanne points out, the PLL following the DDS will give the wanted output plus a variety of unwanted spectral components. The loop bandwidth sets how wide a band around the output frequency can contain quantisation components. The choice of PLL BW is a nasty compromise, you may want to have a wide-ish loop to help clean up phase noise from the PLL VCO, or to get fast frequency changeing, but this lets more quantisation stuff through. Getting a good DAC with more resolution, and expanding the look up table in both dimensions to suit will reduce the amplitude of the quantisation components. Note that many DACs don't work as well as you might think for the number of bits they have, in high speed applications, the glitches created on transitions can be a bigger limiting factor.

Some earlier posts suggested that quantisation components might be confused with phase noise. They are different, discrete spurs at various frequencies, and are quite repeatable and predictable, while phase noise is usually reserved to describe random noise components resembling phase modulation sidebands. DDS's usually give exellent phase noise performance, and loads of quantisation spurs!

I wrote a piece on the tradeoffs in multiloop and hybrid DDS/PLL synthesisers, and finished off with a detailed runthrough of the design and tradeoffs in the ICOM 765 synth, covering just these areas. If anyone's interested its at the end of chapter 14 in the 1995 ARRL handbook.

: DAC. Of course it seems it might be possible to
: seperately convert the lesser SBs as a "bias term" on the PLL output to correct
: for the jitters. Someone wanna analyze that one? (Hint - it's been done before.)

It has indeeed! There are a few reasonable approximations that make the analysis a manageable task, but certainly not fun and recreation. The sort of analogue precision and stability that could be achieved in the "correction" system meant that you still got sidebands formed by the fractional frequency becoming phase modulation about 70 or 80 dB down on the wanted carrier.

Frac-N loops were used on their own for applications that were not critical on cleanliness. For clean synthesisers, they were used to replace the lower significance loops of a classical multi-loop synthesiser, and their output was frequency divided before contributing to the output. Freq division reduces the amplitude of phase mod sidebands by around 20dB per decade of division, and so reduces the effect of frac-N sidebands on the final signal.

(All the people who once designed analogue-phase-correction frac-N synthesisers have switched over to DDS's or to "Noise-shaping" frac-N techniques, and are much happier, now...)

Cheers
David GM4ZNX

From: raymonda@Eng.Sun.COM
Message-ID: <3tegvo$fn2@engnews2.Eng.Sun.COM>
Source record: 112013

I just finished going over the interesting article by Tetsuo Yoshida (JA1KO) in the June 95 issue of QEX.

He states that by not using a constant value resistor for all the stages in the polyphase network, but rather scaling the values by a number arrived at from equation 12 in his article, that the the amplitude response of the network is vastly improved. (See fig 13 on the next to last page in his article.)

I just ran a series of spice simulations on the "4 column" network he describes. I was able to replicate his phase response plots, but haven't been able to get anywhere close to his claimed network attenuation plots. I was wondering if anyone else has looked at this, and has been able to replicate the response shown in fig. 13. When I run a simulation on the circuit using his suggested R's and C's, I get a rising freq. response (about 10 dB over the 40 to 20KHz range) as opposed to JA1KO's flat response. He says his results are a result of measurement, so perhaps we are not looking at the same phenomena. any comments appreciated.

Let's bottom line this. If you want high unloaded Q and also high loaded
Q, put 20 or 30 turns around a toroid and resonate it with a capacitor
or tuning diode to your desired frequency. Now use a 1, 2 or 3 turn
secondary winding on the toroid as your connection to the rest of the
oscillator. It's always worked like a charm for me.

Richard Karlquist (rkarlqu@scd.hp.com) wrote:

: With a high L, small C tank, you can use a low capacitance tuning diode

One problem with this, in the experience of some folk around here whom I've talked with about this subject, is that the tuning diode is likely going to be the lowest-Q part in the tank, and the highest-Q tuning diodes are of moderate, not very low, capacitance. You can put diodes in series, or to some extent tap them down on the coil, to keep a high Q.

Generally, however, I agree with what Rick has been posting on this thread. As a particular example of the "high L, low C, high Q" tank, consider the helical resonator. At least at VHF, they are acknowledged to be volumetrically very efficient at achieving high Q. There are a couple notes about the use of helical and coaxial resonators in Ulrich Rohde and Chao-Ren Chang, "Analysis and Optimization of Oscillators for Low Phase Noise and Low Power Consumption," _RF_Design_, March, 1995, pg 70-79.

Who said anything about the content of the broadcast??? I happen to like the station he's playing, just not the fact that it's coming though my windows and _floors_ at 110db!! And I already said that he's ignored by attempts at reason (most polite by the way...). That seems to leave me with only several alternatives:

1) Call the police. Not an option.
2) Move. Not an option.
3) Pay him a visit with a couple of my friends and a cattle prod. Not a serious option.
4) Find some other way to put an end to his outrageous conduct. A possibility.

In any case, just forget the whole question. I should have realized what the tenor and makeup of a group like this would be <me: ducks>. Seeing the response which included a censored version of my post says it all...

Have fun!

Considering that microwave ovens operate at approximately 2.4 GHz (and I do mean approximately), operating the oscillator mobile will likely wipe out MMDS and ITFS television broadcast for quite some distance. Not likely to be something the system engineers (or the FCC) would ignore for long. FWIW, a pirate MMDS station (2.5 GHz) in Alabama or Georgia was fined six figures about two years ago. They were *not* causing interference.

You guys trying to jam radar are looking a brute force methods, of which none are healthy or effective.

Take some time to learn how radar works, Radio and Electronics a few years ago had an article on how to "Calibrate" a radar gun, not that anyone used it for calibration. "hint : modulate an audio signal on the microwave carrier to make the gun read what you want to calibrate it."

But now most of the guns have a signiture they send out, and only receive that signal, kind of like tone squelch, so the method above is rendered useless, otherwise I wouldn't have printed it.

BTW, I drive 40,000 miles a year, and have no radar detector or any other device, and have not had a ticket for over 5 years.
It really isn't that difficult, it is called effective time management.

A better choice is to use a fundamental-cut crystal and run the output
through a multiplier. Not only will the crystal pull more easily, its
shift will be multiplied through the chain. You might try an inexpensive
20 MHz microprocessor crystal for initial tests.

I'm looking for a low-pass filter with a 150 MHz or so cut-off. A notch filter for 150 to 170 MHz would do the job, too. I need to attenuate 158-159 MHz into a BC-210 scanner I converted to use for 137 MHz weather satellite reception. I'm tuning the scanner 21.6 MHz above the desired frequency after having adjusted the VCO voltage. I need to filter out local 158 MHz pagers and pulbic service stuff. A schematic would do, but would prefer to pick up something I could use.

Thanks. -John (AC4CA)

go to radio shack and get a little cheap book called the engineers mini-notebook for communications projects. in there you will find simple easy to follow directions for transmitters (jammers). I have built one for the fm band to use at work, cool. if you build one without a microphone the person will think that the station is off the air. if you power it with a wall transformer it will generate a loud hum (probably). but if you power it from a battery it will be pure silence. Or you can call The Temple O' the Screaming Electron bbs at
1 510 935 5845 and download the file called (badassja.zip) and it will give you some more info. for fm only. Contrary to popular belief sometimes a jammer is very useful. With an room full of 35 people or so (all with radios) one rude person can ruin everyone's day. Guess the station is off the air today,,,funny I heard it on the way to work. no one knows.

You probably won't find a low pass filter that is close enough to ideal
to really be useful. In other words, a low pass filter with low loss
at 137 MHz won't reject much of the pager signal, unless you use a
ridiculous number of parts. Consider a narrow bandpass filter. I assume
you put in a 30 or 40 kHz wide IF filter as part of your modification.

I did not see the original post, but assume someone wants to temperature compensate an oscillator. One way would be to build a small temperature controller to hold the temp steady. I've never tried it for VFO use, but are aware of a number of controllers suppossed to be able to hold a temp withing +/- 0.001 deg C. One for 37 deg C, was claimed to be able to get to about 5 or 6 decimal places of a degree C.

Hi

Well, I like to know how you design your VCO. I mean, you seem to use a
tapped coil, whereas I planned to use a Clapp oscillator, with a capacitive
feedback.
What is the best choice ?

Afterthought : Do you mean I can still use a Clapp design,
yet, instead of coupling one end of the coil to ground and the other
to the base, I must tap the base connection ?
Like this :

To varicap ------+
)
(----> To base
)
(
GND

And, what is the less noisy : a BJT or a FET ?

Thanks and 73s.

Hi Dave,

Don't know too much about your quest, but I believe you need a Bell 202
or compatible modem. I think this is a 1200 baud FSK modem, and I
believe this is what the baycom people are doing with their kit, namely
using an AMD 7910 "world modem" chip configured to be a Bell 202
compatible. However, there may be more to it than this. A friend has
the baycom kit from A&A Engineering, and the modem pinout for the serial
connector seemed different than what you would see on a regular IBM pc
serial port. Hope this helps.

Hi, all,

I found a 500uA meter movement that I'd like to use, but I can't zero the pointer (it sits on the peg no matter what I do with the centering screw). The meter works, the pointer doesn't seem to be bent, and the centering adjustment works (about 10% range) if I pass some current through the meter to get the pointer off the peg. Any suggestions on fixing this thing? I'd probably just try to bend the spiral spring a touch more to add some tension, but I thought I'd give everyone a chance to tell me if that's a stupid approach. Thanks.

There was an article in 73, CQ or QST recently about converting the
older 1200 baud modems for use with packet. I think it's been in the
last six months or so. I still have it here someplace, I'll try to dig
up the magazine and be more specific.

As far as I can remember the mods were simple and in most cases could
be accomplished external to the modem. Had something to do with P.T.T.
if I remember correctly.

Sorry, I don't remember the software they used. But I think it was
Baycom.

Does anyone have any plans or know-how to convert an old telephone modem into a packet unit? I have several old telephone modems (1200-2400bps) that might work.

It seems to me that a surplus electronics company offered such a deal a while back, but wanted a few bucks for something really cheap.

What software would I run? Baycom?

Please let me know if you have any such plans or where I might be able to find them via the Internet.

Thank You very much.

PS Are there any Ham WWW sites?

In my checking out garage sales, I found a small UV lamp that appears to have been used for looking at rocks complete with ballast and ready to operate. Total cost was about $3 and it takes about 5 minutes to erase the EPROMs.

The Baycom modem kit is available from A&A Engineering for about $60. Comes with pc board, parts, and software, but no enclosure. (about $12 extra, if I remember.) A friend of mine has one, which he has used for about 2 years now. It doesn't have any fancy features, such as a local mailbox, but it works OK. Ramsey's modem seems like the Baycom, but is not in kit form, it is in a serial adapter case that plugs right on to the back of your computer serial port. Note that these are only modems, the software makes your pc do all the other TNC stuff. A$A's address is 2521 W. LaPalma, Unit K, Anaheim, CA 92801 ph:714 952-2114.

2888. I Need a Ceramic Filter from Murata

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-06 00:00:00 UTC
From: geoffs@onr.com
Message-ID: <3thr85$6sg@Sierra.onr.com>
Source record: 112047

I'm slowly starting to piece together enough information to upgrade the ICOM R70 I bought recently. Thanks to everyone who's answered my inquiries about filters, etc. thus far.

I'm looking for a Murata CFS455I or CFK455I ceramic filter to replace the cheapie that ICOM stuck in the R70 as original equipment. I had a Murata catalog many years ago but I've heard that they pulled out of the US market and are now hard to get.

Some repair shops have them but they're quoting prices that are just way out of proportion to their value. I believe that the real value of these filters is around $10 a copy, OEM price.

Anybody got one in a "collection" that you'd want to part with or know if Murata-Erie still stocks these filters domestically? Are there any substitutes?

Thanks in advance.

Geoff NQ7A

It is possible, but I'd recommend you get a radio that is already set up for short wave. If you are not good at electronics the results of such a conversion will likely not be very good
and if you're really good at electronics the results won't be worth the effort.

We have available now a superb super-sniffer kit based around the MC3362 dual conversion receiver chip and the an HC05 family microprocessor.

I won't post full details here unless requested. The cost seems fairly high for a kit....but there's a lot to it and everything including the box and battery are provided. The kit is available for A$226 which is around US$170 ish.

For more details email me at

Assuming they still sell the things, you can get a very good crystal
filter (455KHz) for the R-70 from International Radio and Computers.

Don't have they're number handy, but you can get it from Information
by calling Port St. Lucie, FL (ac 407 I think).

They had these filters in both 2.1 and 2.4 KHz bandwidth (1.6 shape
factor). Might be a "wire-in", but ought to work quite a bit better
than a ceramic.

Look for a second zeroing adjustment mechanism on the other side of
the coil (inside the meter case). It may not look exactly like the
zero adjust on the front side, but it will be cconnected to the end
of the coil spring on that end of the coil. Adjust this one to
zero the meter with the front adjust set to its mid-point.

Unless the spiral spring is obviously bent, I wouldn't touch it -
bending it may cause the meter to become non-linear.

Geoff,
I hate to tell you this, but the Murata filters that you're asking
about are quite expensive. The last time that I priced a CFS455_, the
price was in the vicinity of $45 for quantities of less than 10. These
filters have 9 elements or thereabouts, and the "I" model is 4 KHz wide
at the -6 dB points. And the CFK455_ is a 7-element filter, if I'm not
mistaken.
Murata is still very much alive and well in Smyrna, Georgia. You
cal call them at (404) 436-1300. You might be able to purchase one from
them direct, but they will charge you the full retail price plus shipping.
Even at $45, these are a lot cheaper than crystal filters, which
can cost over $100. But they have the advantage of flatter passband rip-
ple and steeper skirt selectivity.

From: elendir@enst.fr
Message-ID: <3tj9h6$8a1@cismsun.univ-lyon1.fr>
Source record: 112059

Hi
I've got another question.

I have to design the first RF stages of my RXver. For that purpose,
I'd like to use the XXXX (a transistor whose name I can't remember).
I'd like to use it with a source Z of 50 ohms, and a load Z of 50
ohms also, since this scheme does insure stability and low-noise.
But, although I encounter no problem for the first device, how
can I design a network that would transform the Zin of the second
stageinto a collector load of 50 ohms, and at the same time
transform the first stage output Z into 50 ohms .
That is to say a network which, when loaded by the Zout of the
first transistor would transform it into the 50 ohms needed by the
input stage of the second, while at the same time transforming
the Zin of the second stage into the 50 ohms needed by the first stage ?

Thanks,
Vince

I believe I still have some Murata 455khz IF, 10khz BW ceramic filters.
Zin, Zout ~ 1000 ohms.

These are small black plastic cases with thre leads for PC Board mounting.

If these sound like what you are looking for contact by E-Mail.

Chuck

I have designed and used a number of 10,6,2 Meter Dual Gate GaAsFET preamps
with excellent results. With inexpensive devices got 24dB of Gain with
6dB Noise Figure and +13dBm compression point. These will also work on 70cm
just fine.

If you like building your own I have put out a FreeWare (yes free!) for Hams.
Used to sell it commercially but don't have the time for the side business.
You can download it from any Simtel site. You can try the oak.oakland.edu
(ftp)
or www.acs.oakland.edu/oak/oak.html under the msdos/hamradio directory. File
name is KD9JQ_95.ZIP and contains the preamp program ASP 4.0 as well as a
Triode Tube GG Amp program (TAP 2.0) and 4 utilities.

2904. Aviation Headset to Ham Radio Conversioin

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-07 00:00:00 UTC
From: n8tjg@aol.com
Message-ID: <3tjgmq$nd2@newsbf02.news.aol.com>
Source record: 112063

Hi all --
Having a nice David Clark headset (the H20-10) used much too infrequently for aviation purposes, I've been pondering the idea of making a "black box" for hooking them up to my ham radio equipment.

Specifically, I've got Yaesu FT-415 and 416 HTs, a FT-2400 mobile, and an FT-890 HF rig, each of which has a different mic connector, but that is a problem I can solve.

My question is impedance matching and supplying between 8 and 16 volts to the elcectret mic of the headset. The headset earphones are 150 ohm impedance (two 300 ohm wired in parallel), while the radios go with 8 ohms. What sort of coil should I wind to convert the low power audio output, or should I even be concerned???

Second, the microphone impedence is 2,000 ohms on the radios, and the headset is speced as "DC Supply Voltage and Source Resistence: 8 - 16 Volts, 220 - 2,200 Ohms, not polarity sensitive" The headset has separate mic and headphone plugs. So how do I get the voltage to the mic (just stick 12 volts on the plug??), and do I need to reduce the output of the mic before feeding it to the radio, which uses a 2,000 ohm condenser mic??

I know this is asking a lot, but any help will be appreciated. Kindly respond here or by E-mail to N8TJG@aol.com. Thanks -- Alan Williams, N8TJG

: >Thanks, mikkey.

: a EE friend of mine was thinking about taking the microwave part of a broken
: oven and installing it in his grill (shielding rearward of course!). He
: figures that if the police are using a few watts of power, his 1500W trans-
: mitter would effectivly jam the police's radar. (Informational Purposes only)

In addition to being on the wrong frequency, as pointed out by several others,
the thing that breaks probably is in the microwave chain.

I spent quite a bit of time trying to repair a microwave oven that
just quit one day. My first diagnosis was the DC rectifiers were bad.
A replacement cost $40 and had to be ordered. It only lasted a few days.
Turns out that the penny-pinching design causes this to be expected.
When the magnetron ages, it draws less current. The power supply peak output
voltage will go way up under no load. To something like 8KV. This in
turn does in the rectifiers.

My suggestion is to not be the fastest car on the road. Let someone else
trip the radar while you continue on. :-)

A few years ago I spec'ed a Murata ceramic filter for a design I was doing as a freelance engineer. It turned out to be one of the biggest mistakes I ever made. I needed four pieces for my prototypes. Murata would only sell through distributors, and NO distributor I talked to stocked the parts, which meant that I would have to order a jillion of them in order for it to be worth their while. I finally got samples from Murata by begging them once a day for five or six days running.

I have the 140 watt amp kit waiting to be built... looks good, no shoddy parts, good PC board.... that's all I can say for now... those designs are pretty solid, so should be few problems.

Got their giant hunk of heat sink, which I will cut down to about 3/4 size... they have schematics and parts values included for 5 element lowpass filters -- 3 L's and 2 C's, wound on T106 cores. I imagine the usual filters with 2 L's and 3 C's would work as well (ARRL Handbook), and take up less space.

Any good power supply should be fine, though you never know if more filtering of the supply lead could help until you fire it up :-). You'll also need a TR switch... I'm looking at PIN diode setups, and of course switching the bias supply off on receive will keep things cool. No need to switch the whole DC supply off; with the bias removed, it's in Class C and has much lower gain, so it should stay pretty dead (as have lower-power amplifiers I have built.).

I don't have any experience building electronic kits, but find the stuff facinating. I can build a PC, but that's a bit more basic than what I'd like to learn. A year ago I bought an old Heathkit SB-200 amp that works great for me. I know that Heathkit stopped producing Amateur Radio equipment kits, but is there any other place that has taken over the market? Is there any company that has a catalog of amateur radio related kits that are "skill rated" for difficulty? I'm really interested in learning how to build this stuff, but have no idea where to start. Any pointers to help me get started would be appreciated. Thanks in advance!

The germ bulbs from old Maytag dryers work great, if you can find
them (appliance parts store) are about $6. You MUST put a 40W bulb
in series with them. Kurt I would pay $10 for one.

Affordable versions which take advantage of 32-bit operation (386 and new) are:

Intusoft IS-SPICE/386 was $386 years ago; postprocessor (waveform viewer) extra $$
Penzar Development TopSPICE
RCG Research RCG SPICE (cheapest, around $60)

The middle choice sells for a few hundred and also includes digital simulation, while the others are straight 2G6 ports (can do digital in a slow, roundabout fashion).

I believe Microsim (Pspice) and Intusoft both offer "scaled down" versions of their professional grade programs in the sub-thousand price range.

There may be others, but I haven't used them so can't comment on them.

If you really want to go cheap, there are shareware versions on the net that have been compiled for 32-bit operation. I tried one offering and couldn't get it to run.

Sometimes, the reason a crystal oscillator "doesn't oscillate" is because
the transistor is oscillating at a UHF frequency due to base lead inductance,
but you don't know that because you are looking at the output with a scope
that can't detect 800 MHz. UHF oscillations may either "crowd out" the
normal crystal oscillations entirely, or happen concurrently with them,
resulting in erratic operation. The dead give away for this case is that
the circuit is abnormally sensitive to nearby objects. Another test is
to probe the DC base emitter voltage by connecting 1 Meg resistors from
voltmeter leads to the base and emitter. UHF oscillations will lower the
base voltage below the usual .6 V. If oscillations are the problem,
try that old standard band-aid: put a ferrite bead on the base lead.
If you have a spectrum analyzer with a 0-2 GHz. band, you can sniff
for UHF oscillations, but you may not have access to that.

Besides that, you should check for correct DC bias on the transistors,
and then break the feedback loop and drive the circuit with a signal
generator and see if the fed back voltage exceeds the drive voltage
(which is necessary for oscillation). Also, try replacing the xtal with
an inductor and see if you get free running oscillations. If not,
you have a problem in the feedback loop.

Jon:

You could call it an amplifier, then it would oscillate. Seriously, why don't you describe it
more fully for those who don't have a '94 Handbook around. Maybe someone can help. As to the
commercial stuff, I can tell you from my work in a failure analysis department for a large aerospace company, nothing is guaranteed to work:(We spend megabucks helping our suppliers redesign their products to meet the specifications they certified they meet.

>ohms also, since this scheme does insure stability and low-noise.

well, no it doesn't. 50 ohms is merely a convenient reference impedance (actually
with a logical origin which doesn't concern this question); it is not magic. There
is no *guarantee* that a transistor is unconditionally stable with Zs=Zl=50 ohms.

regarding noise, almost always the noise performance is improved if the source
driving impedance *isn't* 50 ohms. this is typically referred to as Ropt or
GammaOpt (depending on the type of device you use and its intended application).
Again, 50 ohms is not a magic number.

Generally for a two-stage RF preamp: input match the first stage to Ropt or
GammaOpt.
How to handle the second stage depends on a lot of things.
>Does the first stage provide a sufficiently low noise figure, by itself, for your desired
receive sensitivity?
--> if so, is power output sufficient to drive your intended mixer at its impedance?
---->if so, probably don't need a second stage
---->if not, design second stage for maximum power gain
--> if not, design second stage for noise as well, using similar process as above.

all the while considering stability of each stage.
also note that maximizing intermodulation performance isn't considered here, it
makes it 1000 times more complicated.

>But, although I encounter no problem for the first device, how
>can I design a network that would transform the Zin of the second
>stageinto a collector load of 50 ohms, and at the same time
>transform the first stage output Z into 50 ohms .
>That is to say a network which, when loaded by the Zout of the
>first transistor would transform it into the 50 ohms needed by the
>input stage of the second, while at the same time transforming
>the Zin of the second stage into the 50 ohms needed by the first stage ?
>

now for the interstage matching network (if you determine that you need two stages).

if second stage is a noise stage, the interstage will transform the conjugate of
(outputZ1) to (Ropt or GammaOpt) of stage 2.

if the second stage is a power stage, the interstage will transform the conjugate of (outputZ1) to the conjugate of (inputZ2) when (outputZ2) is matched for maximum power gain.

But your question...how do you design the thing? it can be done but it's kinda complicated. I wrote a computer program a million years ago (it seems!) to do just that. The particular case you mention (the double match) is pretty darn complex.

if the two stages are reasonably unilateral (that is, the load impedance on a stage doesn't greatly affect the input impedance of that stage) then you don't need to do a double match. the design technique i've described above is pretty straightforward. It's a simple Smith-chart type circuit synthesis to do either of the two cases mentioned above.

If you would like some good references, I can supply a bibliography. However, I don't know how available these books would be in France.

Good Luck!

2924. Oscillator that doesn't.

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-08 00:00:00 UTC
From: acl@ultranet.com
Message-ID: <acl-0707952020230001@amber1.ultranet.com>
Source record: 112068

I recently built a simple two-transistor crystal oscillator from plans in the '94 ARRL Handbook (pg.26-5, Fig. 7). It refuses to oscillate. I've tried more than one crystal, replaced both transistors, and carefully checked the circuit. I also consulted Horwitz and Hill. They note that oscillators sometimes do this, that their own experience is 'well, checkered', and suggest commercial oscillators are a good idea because they're guaranteed to oscillate. If anyone has any suggestions that might activate my proto-oscillator (why call it an oscillator if it doesn't?) I'll try them before I trash it.

Thanks in advance for all replies.

Here is an idea if you don't need to erase something very often,
and I am not sure if it would be effective...someone say something
and tell us if it'd work. Some people like to go to these tanning
salons to get a sun tan. They lay in these UV beds for 15 or more
minutes at a time. If you have a friend that goes occasionally,
give them your chips in a static pad in a box. When they get into
the bed, just have them take the top of the box off and lay it in
a corner that their body won't occupy (like up by their head).
you get the idea...and it is free!...at least they were going anyhow
and there is no extra cost...question is, would it work? Any comments?
This really could be a possiblity for the occasional hobbiest who has
these kind of friends!

: with changes in frequency.

Another way of viewing this type of detector is as a type of mixer. The output is the square of the input, i.e. the signal is mixed with itself. For sinusoidal input, the math works out such that you end up with a signal at twice the carrier frequency plus the original modulation signal plus noise. The capacitor is basically a low pass filter which removes the 2f component. Instead of a capacitor you could follow this detector with many suitable low-pass filters depending on what your aim is.

Perhaps the most interesting AM detector is the synchronous detector which uses a regenerated local carrier. Its design manipulates the math so that the noise component is cancelled for noise components not in phase with the carrier. Again a low-pass filter follows the detector.

2939. Announce: SCALC - a new RF/microwave analyser and optimizer

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-09 00:00:00 UTC
From: Ian G3SEK <G3SEK@ifwtech.demon.co.uk>
Message-ID: <71201867wnr@ifwtech.demon.co.uk>
Source record: 111948

Announce: SCALC - a new RF/microwave analyser and optimizer

NEW RF/MICROWAVE ANALYSER AND OPTIMIZER IS LOW-COST SHAREWARE

S-CALC is a powerful microwave S-parameter analysis and optimization program that doesn't cost thousands of dollars. Developed by Roger Blackwell, G4PMK and Ian White, G3SEK, the SCALC program can analyse the performance of almost any RF network based on standard components and building blocks. Unusually for a low-cost RF design program, SCALC has an optimizer: starting from your initial design, it can automatically improve the performance of the network towards your chosen goals.

As well as having a built-in circuit editor and its own large library of active device data, SCALC can import your own device data in industry-standard file formats. Output from SCALC's performance analyser can be in several formats including colour graphs, Smith charts and tables of gain, impedance etc.

SCALC is easy to understand and use. When G4PMK and G3SEK developed SCALC from the original program ALMOND by Chris Trask N7ZWY, they paid close attention to the user interface and have also produced a comprehensive manual with lots of explanation and tutorial examples. If you already know a little about S-parameters, you can start to use SCALC very quickly because the Shareware release includes the full tutorials and example files. If you're still learning about RF design, SCALC and its tutorials will help you on the way.

SCALC is Shareware with a specially low registration fee for radio amateurs. The registered version also includes a printed manual, libraries of device data and datafile conversion utilities, and technical support.

Requires VGA, 640k, DOS 3.2 or higher.

SCALC.ZIP (152505 bytes) is available by ftp from:

scitsc.wlv.ac.uk /pub/hamradio/programs/g3sek+g4pmk

demon.co.uk /pub/ham/circuit-design

oak.oakland.edu /pub/hamradio/pc/ham-utils

and also from the CompuServe HamNet library.

On disk, SCALC is available from the following UK shareware libraries:

Venus Electronics

Public Domain & Shareware Library.

2944. DDS/PLL Hybrid theory

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-10 00:00:00 UTC
From: osbdivgp@yarrow.wt.uwa.edu.au
Message-ID: <3tq7jh$1ir@styx.uwa.edu.au>
Source record: 111953

I have been reading with interest the discussion on this topic.
Have already tried this idea using a PIC 16C57 micro as the DDS .
The controller reads a keypad to get the frequency data and then goes
into a software loop which acts as the digital adder. Using a 16 bit word
the controller can produce 2^16 /2 steps ie 32768 up to a frequency of
about 250 KHz at a max clock of 20 MHz. In practice I used a 11 MHz
(because I had the crystal!) clock. The MSB of the adder was used to
drive PLL loop with a VCO running on 14 MHz. A CMOS divider and a 4046
phase detector and a loop amp completed the PLL. With a loop bandwidth of
about 50 Hz (2nd order loop) I got 400 Hz steps at 14 MHz.
Using a spec analyser to look at the output it was almost acceptable for
amateur use with 400 Hz sidebands down about 35-40 dB.

This could probabaly be improved by better loop design (it was preety rough)
or a higher order filter.
I tried a 24 bit version with approx 1 Hz resolution but this was noisy
due to the close in sidebands (ie about 1 Hz) and the signal was
unusable.
Hope this gets posted as I am a newbie - havent worked out all the
Internet conventions yet

2945. WTB: or info on HF QRP amplifier kits (5W in - 20 to 30W out)

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-10 00:00:00 UTC
From: bad@ee.WPI.EDU
Message-ID: <3trvgd$8jb@bigboote.WPI.EDU>
Source record: 111954
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew

I built the A&A Engineering 30 meter 5W QRP rig. There is plenty of room left inside, so I would like to try to add a small switcheable amplifier for 20-30W output (with 5W in from the rig).

Only problem is that all the kits that I have seen have a maximum of 2W in before they get overdriven. Does anyone know of a company that markets compact kits of HF amplifiers that are capable being driven by 5W on 10.1 Mhz. and deliver 20 to 30W of output (must be a 12W capable amplifier, preferably class C since it's CW only and efficiency is important).

Thanks for your info/help.

You have lost me a bit there, but I'll do the best I can.

Desiging a network to match any complex impedance to any other is simple. All you need is an L-network. I have a program (PC) I wrote to do it, which I would share if you wanted. The other way is to make the impedance real (add series L or C) then transform the one real impedance to another. There are lots of ways to do it. Eg Pi, L, T networks. There should be a program published in EDNs 'Design Ideas' soon to do it. I wrote the code, but cant give it to you (as they paid me). All networks can do the job, its just some are more practical.

The problem I've had in the past is that S-parameters assume the device has 50 Ohm loads on all ports. Since S12!= 0, matching the o/p to its conjugate for maximum power transfer means the input Z will change. Even if you calculate its new value, and match the input, the output matching gets screwed up. So you re-match the output, but then the input match becomes poor. In other words, it becomes an iterative process. I've never found a definitative way to do it quickly. (I posted a request recently for a decent way, but got no replies).

If you have two stages, there is no need to go via 50 Ohms, although I admit it makes testing easier.

You imply the devies are stable and low-noise at 50 Ohms. Most devices have an optimum input Z for lowest noise. You cant assume its 50 Ohms. Its usually put on the device data sheet as TOR_opt (Greek Tor). You should try to make sure you input device sees this reflection coefficient, rather than 50 Ohms. Its easy to convert from tor to Z.

If the device
is not unconditionally stable, then you have to be careful what load it see's. Again assuming 50 Ohms is okay is not really on. You need to calculate a couple of stability factors. One will tell you if its unconditionally stable, in whcih case your okay. If not, you have to be careful. See 'Microwave Mesfets' By Pengelly, for how to do that.

Hope this is of some help. If you want the program to convert one arbitrary complex impedance to another, please let me know. I'll put it on our ftp site. I should add there are a number of Application notes by Mototola and HP on this sort of thing. I'm no expert, but have managed, with a bit of fiddling/luck/insight etc to design a few amps to be stable and have good return losses.

I've had pretty good luck with a single shorted halfwave notch filter. It
was a halfwavelength of coax inserted into the receiver antenna transmission
line via a T connecter and shorted on the end. Tuneup was performed on
the bench by inserting a shorting pin in the coax to find correct the length
and then cutting the cable and soldering. It was pretty dirty but took
care of the problem with only one trip to the store!

In your case you may need one resonator per offending transmitter which can
get out of hand in a hurry. In that case, you will probably want either
a bandpass filter for the desired frequency or a better designed band
reject filter.

Source record: 111959

We had some students working on a 10GHz data link project a few years back, using the Handbook design as a starting place. They were trying to make it be a 10 Mbps ethernet link rather than 2Mbps, and ran into real problems dealing with the ethernet collision sense signal. I don't recall what problems they might have had with the MC13055 receiver chip, but they probably had some. Our experience with the one-chip receivers has been that they all *inevitably* have problems! If you send email to my colleague Rob Frohne (frohro@wwc.edu), who supervised the project, he might be able to give you some tips (after he gets back from his honeymoon in Thailand in a couple of weeks).

I would like to get some students going again on the ethernet link project, so I
would be interested in keeping in touch with you on your attempts.

Good luck,

A friend has a IC 735 which he wishes to interface with his PC. He has the software but not the interface nor any detail about it. He does not want to buy the genuine Icom one and believes that it only needs a level convertor. Any help or information would be appreciated. If there is a mod file somewhere can you provide the FTP address.
Thanks..Dave G3VUS

Dave Kirkby (davek@medphys.ucl.ac.uk) wrote:
[...]
I think I have been a bit confusing. Let me put it this way :

The choice of 50 ohms source and load is not innocent. For this
particular device, 50 ohms real impedance produces stability, since
|s11| and |s22| are both < 1.
Then I have no clue about Gamma OPT for this transistor at 150 Mhz. All I
have is a curve that shows NF in a 50 ohms system, and I can read a NF < 0.8 dB.
Therefore, I selected 50 ohms both Zs and Zl.
Since this is the first stage of a RX, it allieviates all need for a matching
network between the antenna and the base (I use 50 ohms elliptic filtering
though).
But now, I'd like to add another RF stage, based on the same device, and also
with a 50 ohms Zs and Zl, since it seems a reasonable course (as would say
Spock).
Now, the problem is this :
Not only must I transform the s11 of the second transistor in order that it
appears being 1 (This ensures Zl of the first stage as being 50 ohms), but
I must also adapt the s22 of the first stage into 1, as to have a Zs of the
second stage being also 50 ohms.

A sketch :

ANTENNA ---- STAGE 1 ---- NETWORK---- << APPEARS AS 50 OHMS
APPEARS AS 50 OHMS >> --- SAME NETWORK ---- STAGE 2 (IDENTICAL TO STAGE 1)

Therefore through the same network :
s22 of the first device should be 1
s11 of the second device should be 1 also.

I know how to make a unilateral match, but this is a bilateral matching
problem.

Any clue ?

I would say, forget the impedance difference on the headsets. I use
600 ohm headsets on "8-ohm" outputs quite frequently, and the only
problem is that it's sometimes a bit faint.

> Second, the microphone impedence is 2,000 ohms on the radios, and the

> (just stick 12 volts on the plug??), and do I need to reduce the output of
> the mic before feeding it to the radio, which uses a 2,000 ohm condenser
> mic??
>

If your radios don't provide condenser mic current, you can put about
a 1K resistor from the headset mic hot side to +12V, and a 1 uF cap
from there to the radio input to decouple the DC. Connect the ground
side of the mic to the radio ground, of course.

I've made an interface for my D-C headset (I'm also a pilot) to connect
it to my IC-2GAT handheld. In this case, the radio provides DC feed
for the mic, so all I needed was a PTT switch in series with the hot
lead of the mic. It works like a dream. (Ever try 2m simplex from
10,500 feet???)

>mininec anyway.

I don't know about the relays, but my new 5-band quad should be
arriving any day now...
Here's what I plan for feeding: bought an Amidon 2:1 balun,
connect all 5 bands in parallel through this balun. I believe that
this should match very well (my belief may become modified in a
month's time by actual experience, though <bg>).

Incidentally, the Amidon lineup of baluns appear really crappy
from a mechanical/weatherproof viewpoint. I'm sure the innards are
well engineered, construction seemed average, but the folded aluminum
box with open seams everywhere really sucks.

Hi folks,

Several years ago I built a homebrew EPROM eraser based on a 40W germicidal tube, and it works a treat. I can erase a whole batch of chips in 5 minutes. I have found though, using these higher power tubes a high failure rate of EPROMS. The devices are erased but will not program correctly. These chips may have been cycled only a few times before failure.

I put this down to the high exposure rate. Commercial erasers here take the best part of an hour to completely erase, and you do not see "5 min erasers" on the market.

SoI hope my experiences may help those who are building an eraser to be aware of some of these tubes.

Hi Steven,
Weellllll... Seems like this is a old story. I can remember hearing the
same thing as a young novice back in the 60's. The only application I
know of is to wind a few turns of insulated wire around the loopstick
antenna in the BC radio, and rely on the harmonics of the local
oscillator to bring in *lots* of stuff from 1-? MHz. No selectivity to
speak of, but kind of a fun experiment.
Why not try your hand at a simple regenerative SW RX?
Let me know if you have any luck!

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
July 16th, 1995
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Source record: 111874
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew

Hi Bernie,

3 options come to mind of the top of my head. The first is to contact Ten Tec in Tennessee. They recently released a line of kits and I seem to remember that one of the kits was a Power Amplifier stage from their now-discontinued Argosy2 HF rig. It is a 50-watt PA, and input drive is about 5 watts. Perhaps you can drop your drive down to 3 or 4 watts to get your needed 30W out.

Another option is to use a CB-radio "mosquito" amplifier. These amplifiers typically were designed to "nudge up" the power of a CB (illegal in USA) beyond the 4 watt output. Typically, the "mosquito" amplifiers ran in the 30 to 35 watt output range and would operate all-mode (ssb/am/cw/fm). I'm sure they are available but cant advise where. Though designed for 27 Mc, I know of guys using these with their TenTec Argonaut 509 and 515 QRPp rigs with fine results. It requires changing components but that's all. Price should be under 50 US$ for one of these units. This is NOT a high power, 500 watt super QRO thingamajob. just a mild boost.

The third option is to consider a commerical amplifier. In Japan, Tokyo Hi Power was marketing a 3 band QRP digital transceiver operating on 7/21/50 Mhz. The rig ran 3.5 watts PEP, and, you can purchase a 20-watt tri-band amplifier already made.

I know of no pre-manufactured solid-state amplifier kits in the 20 to 30 watt range that can safely be driven with 5 watts of input power.

Is your objective to listen to shortwave, modify the radio or a little or both.

The latest issue of Popular Electronics has plans for a SW converter, to listen to shortwave on an AM radio. This one has it's own tuner so the 10 Kz steps on digital radio's doesn't matter, ideal for a car radio.

If you want to build or modify something, then use it yourself this may be just the ticket.

If you just want to listen, but still want to use the AM radio there are several commercial converters available. The first that comes to mind is one by MFJ.

Glenn Sparks who is not associated with Popular Electronics or MFJ.

The trouble is, 1200 baud packet uses the Bell 202 statndard, while 1200
baud telephone modems used the Bell 212 standard.

But then maybe somebody knows some tricks that I don't!

2970. MF-HF preamps

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-11 00:00:00 UTC
From: kevinm@mail.utexas.edu
Message-ID: <3tu2r7$9f4@geraldo.cc.utexas.edu>
Source record: 111879

In years past, I built HF preamps using a Siliconix VMP4 in a single-ended configuration described by Ed Oxner in _QST_.

These were wonderful amps -- the third order input intercept was around +40-50 dBm, and the noise figure was about 4 dB. The only drawback I ever found with this design lay in the extremely heavy doping of the VMOS FET itself which made the VMP4 subject to gate puncture. Practical designs thus required some care to minimize this possibility.

Siliconix exists no more, so my question is: is there a similar device on the market now that will in some configuration give IMD and noise figure similar to those above?

I'd appreciate any references, schematics, etc. anyone might have. If the VMP4 is still available (I heard Siliconix got sold to MaCom), where can I get them?

Thanks in advance.

> Steven H. Schimmrich

May be it would be a good idea first to clarify the question.

The majority of AM radios are *designed* to receive short wave
broadcast transmissions. So may be the question was about receiving
SSB transmissions? (build a 455 kHz oscillator and operate it near the
set...)

If the question is on receiving short wave transmissions on a medium wave
radio, the answer is: the use of a frequency converter is only possible
with a well shielded car radio type set, with *no* ferrite antenna.

good Luck, Moritz DL5UH

The 1994 ARRL Handbook for Radio Amateurs lists the VMP4 as a M/A-COM
device. I don't have M/A-COM's number but one could try 800 directory
assistance for starters.

Well, yes. I did it once, and it worked pretty good until I took it apart and ventured on more :) OK, what you do is, take the AM coil, inside the radio. Unhook it, and replce it with 7 turns of #28 (I think) enameled wire. Attach an anteena to the tuning know legs, just hold it up to one until you can hear a difference in the signal on AM. Now, you can solder it all, and you should have a half-decent SW radio...Make sure the radio's somehow grounded...It dosn't matter, but it REALLY helps. I'm not guareenteeing this will work, it's been a long time, but it should. Have fun, KB0MMU, Andy.

Dan,

The tough part is finding a suitable transformer. 12-volt supplies are
popular, so power transformers in the 16-18 volt range are in demand.
You could also use something with a 32 to 36 volt center-tapped secondary.
Rectifiers, filter caps, etc. are easy to get and reasonably priced.

For a regulator, a bunch of 2N3055's in parallel are cheap and effective.
I used a 7812 IC regulator to drive them. The 1994 Handbook has a
28-volt 10-amp project writeup using 2N3055's in parallel. Make sure
you have 3 caps on the 7812's output lead; one good size electrolytic, one
tantalum and one disk. Without them the power supply becomes an oscillator.

If you have any other questions, just email. Power supplies are great
projects.

Xmit_ID version 1.60 shareware

Due to the interference problems that plague larger and even smaller repeater systems. Finding those people responsible can be very difficult. Yes you can DF them. Now you need to be able to prove it. The answer, "Finger Print" the radio. The price of this equipment can be out of reach for the average ham. Now with a modified radio, a used 386 computer, VGA monitor, 1 meg of memory and a Dos compatible sound card you can get "Finger Prints" of radios. This program with store them and compare them. It can be download on the internet from ftp:oak.oakland.edu /pub/hamradio/pc/ham-util/xmit160.zip or on Compuserve in the ham net form Software & Pictures directory XMIT160.ZIP. The cost to register this program is only $15.

Hello all,

Does anyone know if there is a way of calculating the feedback capacitor in an emitter follower oscillator with a crystal from base to ground? That is with the capacitor from emitter to base.

Also, is there a way of calculating the expected amplitude at the emitter?

Any help is much appreciated.

Ian

siva@bond.bocaraton.ibm.com (Chander) asked, on erasing Eproms:

CR> How about the black light bulbs available at Home Depot?

No good. These are LONG WAVE UV lamps. They will not erase the chip.
You need SHORT WAVE UV for that.

You can also look at long wave UV without hurting you eyes, but when
you do, they feel strange. You know you are looking into something that
appears to be quite dim, but your eyes tell you (by the way they feel)
that you are staring into something very bright. Quite odd.

CK>I put this down to the high exposure rate. Commercial erasers here take
>the best part of an hour to completely erase,

Correct. There is a rate at which these chips must be discharged. If
you use too high an intensity of UV, you will damage the chip. There
was a high speed eraser available several years ago, which looked like
a camera flash. The strobe tube was made of quartz instead of glass to
allow the short wave UV to pass. You placed this device over the chip
window, and only flashed 2 or 3 times to erase the chip. Blank in
seconds. We never bought one because we though the intensity would
damage the chip. We later heard it did, and even chips which had been
erased several times, and reprogrammed OK, were failing in the field
after several months. Apparently the cells were somehow damaged and the
charge was leaking out, and the contents of the chips were changing
(call it self erase).

Ian,
From a practical standpoint, the tank circuit in a Colpitts or
Hartley oscillator (yours sounds like a Colpitts), the capacitors and
tank inductor roughly form a matching metwork between the emitter and
the base. This is why a Hartley is a better choice for a wide band-
width oscillator, as you essentially have a tuned autotransformer for
a tank circuit.
To derive these values, you need to know the crystal impedance
as well as the impedances of the transistor, assuming that you want to
be exact. Otherwise, you can take a stab at the emitter to ground cap-
acitor being approximately twice that of the base to emitter capacitor.
This, of course, is just a rough rule of thumb.

I won't hazard a guess as to the output amplitude. I'm usually
thrilled to get anything at all (Hah!).

Source record: 111895
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Hi Folks
I got these plans from someone via E-Mail. I haven't built this antenna yet, so I have no idea how well it will perform. (Please note that when the plans refer to rg-93 coax, I believe they mean RG-62.)

Please, If you build this antenna I would love a quick E-Mail to see how you made out!

Begin Pasted Text:

Date sent: Wed, 14 Jun 95 12:53:10 CDT
From: harper@huntsville.sparta.com (Christie Harper)
To: dsantoro@pipeline.com
Subject: eggbeater

For a more omnidirectional antenna you might try what is known as an "eggbeater" there are commercial versions available for $110 or you can
make one for about $5. the eggbeater is comprised of two full wave loops
placed perpendicular to each other and driven 90 degrees out of phase. this gives the antenna a horizontal component along the horizon and a circular component overhead.

looking at the antenna from the top it would look like;

```
|
|
|
|
----------+----------
|
|
|
|
```

Use a piece of pvc pipe as the mast.

Make two full wave loops (length = 299.8/F (Mhz) Meters) using #12 or heavier wire.

A full wave loop has a "resistance" of about 100 ohms so resonate the loop
at the desired frequency by doing the following;

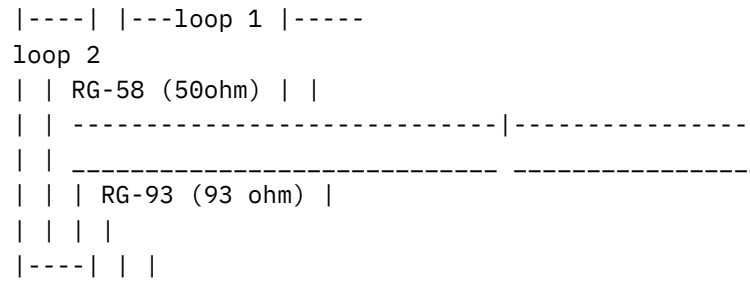
use a quarter wave 75 ohm matching line (50-100 ohms). Cut the loop one or two inches longer than calculated and keep pruning to resonance.

drill holes in the pvc to pass the loop (NOTE insure that the loops DO NOT touch at the top or bottom.

Phasing harness..... need a 1/4 wavelength piece of 93 ohm coax

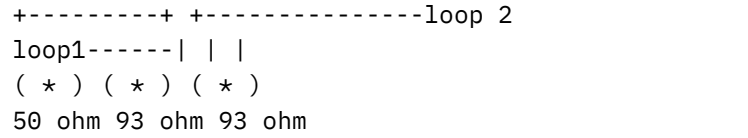
length = 0.25*(velocity factor)*299.8/Freq (Mhz). Velocity factor is available in most handbooks (coax is RG-93).

---- braid
____ center conductor



favorite
connector

An easy to mount the phasing line is to take a small piece of circuit board (radio shack) and drill three holes in it and attach cable as follows.



solder all shields to the circuit board. connect short jumpers from the circuit board to the other sides of the loops.

Based on homebrew work of W3PM (Gene Marcus)

I've built a couple of the ARRL Handbook GaAsFET preamps.
The device is static sensitive and I've lost some on the bench, I now buy several at a time.
The tuning caps need to be high-quality, as drifting values will change gain, and matching.
A fully closed, rf-tight box is needed if you live in an urban area with lots of mobile radio traffic. These make construction easier, you build the circut on copper sheet attached to the lid. Mount connectors through the board, easy access.
Make sure you use some interlock or sequencer to avoid destroying the active device. I got lots of practice building these until I built the sequencer appearing in the handbook.

Source record: 111897

I was thinking of building the regenerative receiver on page 17.68 of the 1995 ARRL handbook. Has anyone else built this? Any comments or construction hints? Thanks.

2989. Looking for oddball parts

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-12 00:00:00 UTC
From: Pete Goudreau <pgoudrea@lsi.dsccc.com>
Message-ID: <3u0qki$rfd@tpd.dsccc.com>
Source record: 111898

I've an old National NC-57 that uses a peculiar pulley and string arrangement to couple the tuning knob and dial to the variable cap. The string is anchored to one of the pulleys through a small spring, wraps out and over the pulley to the other pulley and back where it drops through the slot and is anchored to the face at a tab. I need to use this arrangement on another project and have no idea who to call to find these types of parts. Any help will be > appreciated.

Thanks,
Pete G.

Sorry 'bout the addr mixup....here's the text I got...

Subject: Re: Re: Soundblaster CRO

I have posted it in the public directory of the gateway here in town.
You can log in as anything to download it.

The filename is fftscope.arj and it is about 100K long.

You can FTP connect to either une.vk2djg.ampr.org (44.136.32.1) within
Amprnet or vk2djg.une.edu.au from Internet (the same machine)

I just had another look at it and am impressed once again. You can do
accurate measurements and I especially like the spectrum analyzer
functions.

Have fun!

2991. Need reference for VHF/UHF yagi book

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-12 00:00:00 UTC
From: willmore@MCS.COM
Message-ID: <3u15qu$dd@Venus.mcs.com>
Source record: 111900
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I'm looking for a good book on yagi antenna design that doesn't spend the whole book talking about HF tri-banders. I'm interested in 2m and up. I live in an appartment and space limitations and the landlord don't allow for HF operation. Living on the ground floor, an omni doesn't work too well. I need gain and I need it in a reasonable size.

I have been looking for a decent book (w/software would be nice) on Yagi design considerations for the upper bands. I'm a Computer Engineer, so I don't like field equations, but they don't scare me. :) Theory is fine as is practicality. I'm supprised that there isn't more available on the topic as 1/2" copper pipe is relatively cheap--$3.50(US) for 10". That's three 1/2 wave elements on 2 meters.

BTW, is there a good FTP site for antenna design programs. I keep hearing about NEC and the like, but I have no idea if these are commercial or PD nor how about getting them. If anyone could help me out, I would appreciate it. I'd really like to whip up a 6 element Yagi for 2M using 1/2" copper this weekend, but all of the 'construction' articles I can find sound like:

"build it this way, cut everything to the nearest 1/10th mm and file it to tune it--oh, and don't forget to do this in free space wearing teflon underware!"

Can anyone suggest anything for me to try--a place to look, a book to find, a new degree to get, anything?

Cheers,
David

2995. PIC Programmers starting at only $29!

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-12 00:00:00 UTC
From: itutec@aol.com
Message-ID: <3u1duu$fpl@newsbf02.news.aol.com>
Source record: 111904

ITU Technologies is proud to introduce the ITU PIC Programmer, the first truly low-cost and versatile programmer for the Microchip Family of PIC microcontrollers. This programmer is designed for programming Microchip's PIC16C6x/7x/8x microcontrollers. An 18-pin socket is provided on board and 28/40 pin adapters will also be available. An expansion header is provided for adapters and in-system programming of EEPROM-based chips.

SPECIAL INTRODUCTORY PRICING FOR INTERNET CUSTOMERS
For a limited time, this special introductory pricing is available:

ITU PIC Programmer (Model PIC-1) KIT $29
This kit includes:
* an easy to read instruction manual for building your programmer
* a high quality printed circuit board with silkscreen
* all components needed to build the programmer
* PIC Programming Software for IBM PC-compatible Computers
* a cable to connect the programmer to a PC's parallel port
* a power supply for the programmer
* a User's manual introducing PIC programming to the beginner

ITU PIC Programmer (Model PIC-1) Assembled/Tested $49
As above, but assembled and tested.

ALSO AVAILABLE PIC-N-GO PACKAGES:

PIC-N-GO packages are designed for the microcontroller novice. They include the ITU PIC Programmer (Model PIC-1) as above plus a PIC16C84-04/P microcontroller. This EEPROM-based microcontroller is ideal for the novice and the PIC-N-GO packages are the most attractive programmers available for the beginner. These packages are great for students and hobbyists looking to acquaint themselves with microcontrollers.

PIC-N-GO KIT only $39
* includes PIC-1 programmer kit and PIC16C84-04/P microcontroller

PIC-N-GO Assembled/Tested only $59
* includes assembled and tested PIC-1 programmer and PIC16C84-04/P

All products include a 30-day money back guarantee and a 90-day warranty. Due to the nature of kit building, kits must be returned unassembled to qualify for a full refund.

We are currently unable to process credit card orders, but pre-paid and COD orders can be handled. Quantity and student discounts are also available. Please e-mail us at ITUTec@aol.com for ordering information.

Questions? Please e-mail us at ITUTec@aol.com!

Jon-

I'm not familiar with your specific oscillator. In general, oscillation requires a circuit loop gain greater than one. Some kind of voltage divider is often used to feedback a sample of the output, to reinforce the oscillation. It may be in the form of two capacitors, or it may use a tapped inductor.

By changing the ratio of capacitors, or moving the tap on the coil, you should be able to find a point where the circuit oscillates. (Excessive feedback may distort the waveform, causing most of the output energy to exist at harmonic frequencies!)

Hi Mike...there is some construction details on a 1296 Power/SWR
indicator in the new ARRL UHF/Microwave projects manual, originally
an article from Nov. 1980 QST. Other than the Pc board microstips used
for the sensing, the rest looks straightforward.

: Also, is there a way of calculating the expected amplitude at
: the emitter?

The answer to your questions is "yes".

However, there are very many variables to consider: desired stability, frequency, aging, cut of the crystal, transistor gain, etc.

Your best bet is to refer to the book "Crystal Oscillator Design and Temperature Compensation" by Marvin E. Frerking. The book is published by Von Nostrand Reinhold, ISBN 0-442-22459-1. This book is a "must read" for anyone who wishes to build a high-performance crystal oscillator.

Source record: 111911

Hi John,

Don't know about the modem, but if you can get hold of JVFax, Hamcomm, or something, the modulator for this software (with a very small modification) will run packet. The trouble is
it requires 2 com ports, and then you run Baycom with EMBAYCOM, a little addition that's around. This will run packet and I use it myself.
One complain, though, Baycom is not only written in German (and Embaycom by a Russian guy!!)
but I seem to be having a bit of trouble with the software (every-so-often it sends a disconnect request for me!!!!). Apparently others do OK though.

Most FM stereo receivers can be tapped right at the output of the
FM demod (before the stereo decoder IC and de-emphasis network)
to get the broadband baseband you need for your SCA decoder.
You sometimes need to render the stereo decoder IC non functional
so that the harmonics of its own 19 or 38KHz oscillators don't
interfere with your SCA signal.

I have done this with good results on a number of receivers. You
might try one of those cheap walkman style units. Access to good
IC data books will help you find the right point to tap.

I think I can help. It was designed here at Ericsson Inc. in Morgan Hill, Ca by Jeff who works with me in the Engineering Dept. It's manufactured here too. We have transistors in that band delivering from 1W to over 150W CW. The 20093 will do an easy 9W with 10dB gain and min. 50% efficiency. It will handle an infinate VSWR too. It is not a 50 ohm matched transistor, so some impedance matching will need to be done on the PC Board to get it to play. Circuit diagrams are readily available and the circuit is not complex.

Drop me a line I'll send or fax you a data sheet. I would also like to know a little more about the publication ATVQ if you don't mind. I've been involved with ATV here for only about a year or so and am looking for some good publications. Thanks.

>there yet, (ha). The Amidon literature for me is confusing....
>Thanks!
>Dan Reynolds, bcdlr@aol.com, KB9JLO

I've written a program that will do the first part, calculate LP filters (along with HP, BP, narrow BP (Top-C coupled resonators) BR, elliptic HP and elliptic LP). I've placed the program in the public domain. I won an honorable mention in the RF Design magazine annual contest back in '91 with a really rough version of this program, and have continued to work on it and update it. The program is called FilDes, or FDS.

It is available via ftp from ftp.netcom.com in /pub/rander. The last time I checked was a few months ago, so let me know if it isn't there. IF you find it elsewhere, the current rev. is 1.24.

If you run an ftp site, and would like it, let me know your address.

As for winding Toroids, I've always just used the Amidon data. There is a different Al for every size core in every mix, which is a big lookup table. Once you get used to it, it takes a few seconds with a calculator. Ferrite beads? Most of the time you just run one or two turns through a bead. It is usually not critical. If it is critical, the construction project should tell you.

BTW, if you are using ARRL Radio Designer software, my program will write a Touchstone format circuit file of the filter you design. I'm told (by the ARRL) that a translator is (will be?) coming with Radio Designer that will allow you to read the files my program writes into Designer.

>mod file somewhere can you provide the FTP address.
>Thanks..Dave G3VUS

It does indeed only need a TTL to RS-232 converter. The send and receive take place on the same line, so I used a simple pair of old, low tech chips (hey, I had them on hand) MC1488 and MC1489. A newer part like a MAX232 will work just as well.

Sorry, don't know of an ftp site, but it's pretty easy. Your PC has a Tx and Rx pin, you hook those to a line driver and receiver, respectively. The outputs are tied together, and to the wire to the rig. (Use shielded wire, or RG-174 style coax to keep the RF out of your computer - and the computer out of your receiver.)

Hope this helps.

73,
Bob

The "probe" picked up the 4.5 MHz sound IF signal from outside the TV. It was a small plastic box that probably contained a ferrite resonant antenna tuned to 4.5 MHz. The customer was instructed to move the probe around the outside (usually underside) of the TV until it picked up a good signal, then plant it there with the provided double-sticky tape. Don't laugh. It actually worked quite well. The Recotron box then processed the signal thru a TRF receiver with FM demodulator.

The MPX input, as you guessed, is for a full composite audio signal. Some TVs in the early stereo era had an RCA jack on the back outputting this signal. Do not try and tap this signal out of the TV unless you are *certain* it is isolated from the AC line. Most TV's, especially, low-end models rectify the power directly from the AC line without a transformer, so the entire TV circuit is at line potential. VCR's are much safer for such hacking as they are almost all powered internally by low, isolated DC voltage.

Mike,

Thanks for the (quick!) response. Another question: If I were to use a
demodulator to step down from, say, channel 3, would that provide me with
either that 4.5MHz or a way to get the full composite audio signal?

Thanks,
Jeff

3017. quick-release harness for mobile rigs ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-13 00:00:00 UTC
From: sheppard@ruby.decatl.UUCP
Message-ID: <SHEPPARD.95Jul13101935@ruby.decatl.UUCP>
Source record: 111915
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Can anyone point me to:
(1) a commercially made product
or (2) useful homebrew hints
for a quick-disconnect harness for a mobile 2M or dual-band rig ?
(The rig in question is a Yaesu FT-2400).

I remember hearing of such a beast once but don't remember the source.

My intention is to ease the transfer of the rig between two vehicles
and a fixed base station. I envision identical pre-wired docking bays
permanently installed at each location to provide power, ground,
antenna (and control ?) connections, and a corresponding low-profile
harness permanently mounted on the rig itself.
Mods to the rig are probably inevitable (sigh).

The prime issue here is speed and ease of connect/disconnect, not security.

Thanks in advance for any pointers, information or suggestions !

3018. S-paramater problem. Am I going mad???

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-13 00:00:00 UTC
From: davek@medphys.ucl.ac.uk
Message-ID: <1995Jul13.111409.31930@ucl.ac.uk>
Source record: 111916

I've designed and build a small amp using an MRF136 (power device, but I'm using at low power) using S parameters. The theoretical S parameters of the completed circuit (not the device) at my frequency of interest (82MHz) are:

S11=-24.4dB @ 116.1 deg
S21= 16.07dB @ 29.4 deg.
S12=-28.8dB @ -50.3 deg
S22 = -21.51 dB at 172 deg.

The built circuit is not quite as good, but shows 15.3 dB gain and reflection coefficients of about -13 and -22 dB. Since I dont have an S-parameters test set (I'm using spectrum analyser and a directional coupler) its a bit tedious to tune up to maximise gain, minimise S11 and minimise S22. A decent S12 would be nice too!

When analysed theoreticaly the completed amp is unconditionally stable, so I thought I could probably make S11=S22=0 at my design frequency. This was my thory, but it dont work. Can anyone see where I've gone wrong??

------------------Theory--------------

According to a book (Microwave MESFETS by Pengelly):

The input and output reflection coefficients of the circuit vary depending on the source and load relection coefficients as:

Tor_in=S11+(S21 S12 Tor_l)/(1-S22 Tor_l)

where Tor_in = is the reflection coefficient seen at the input.
Tor_l is reflection coefficient of the output load.

(ie when you load in a perfect match, you see just S11).

also:

Tor_out= S22 + (S21 S12 Tor_s)/(1- S11 Tor_s)

where Tor_out is the reflection coefficient that would be measured on the output.
and Tor_s = is the reflection coefficient of the load at the input.

I then tried solving two simultaneous equations:

Tor_in=0 and Tor_out = 0 for Tor_s and Tor_l.

I get (according to my Maths program):

Tor_s=S22/(S11 S22 - S12 S21) and Tor_l=S11/(S11 S22 - S12 S21)

I assumed that if I built networks to transfer the 50 Ohms to Tor_s and Tor_l.
I would be able to simultaeously match both input and output. Unfortunately, after

simulating them, it just does not work! I can match input or output, but cant do the two together. Since I solved a set of simultaneous equations, I cant see whats gone wrong. Any ideas?

Dave Kirkby G8WRB.

> KW5Q
>

I dont suppose you need the low noise figure for HF, but I've recenly investigated the MRF-136 from Mototola. Its a 15W output FET, which would indicate to me the output intercept should be >50dBm. The typical noise figure is 1dB. Be aware, I dont think the 150MHz test circuit given in the data sheet will give 1db NF, as it uses resistive loading for stabilisation. However, you should be able to use it with care. I managed to at 82MHz. It coss #14 in the UK, so you might consider it overkill. It needs 28V @ upto 500mA. I'm thinking of using one for a lowish noise 2m preamp.

>for HF operation.

Hi David,

Well there are good and not so good designs around. Before thinking about
a yagi, you shold be sure you have a place *in the clear* to put it up.
If it sits between houses, only a very short antenna (three element
or cubidal quad) will not suffer excessive degradation of its radiation
pattern.

I can't see that 1/2 " copper pipe is particularly suited for yagi
construction, you have to varnish it (and maintain the varnish
in good shape) and use a fairly beefy boom to carry the weight.

If you design a yagi, a good idea is to go for a feed point
impedance of 50 Ohms and use a folded dipole with cable balun.
Its a sure-fire no-tune method. (see K1FO)

>>> AN ERA PASSING
The first issue of MLH was distributed in January of 1993. Two and a half years later, I expect this to be the last MLHacker. I still use my minisports regularly, but the seasons change, time moves on, and other facets of life become dominant. I also picked up two broken laptops (a '386 and a '486), and, by mixing and matching parts, I have a '386 that is capable of taking over much of the Minisport functions. Prices are falling such that it's become reasonable for me to begin using a more modern laptop. The two minisports are getting attention from the kids. They have favorite CGA games, and they're beginning to call the Minisports "their" computers.

MLH has been coincident with me learning a lot about the Internet and Amateur Radio networks. After swelling my activities to the point where net surfing was all I was doing, I've shrunk back to a level where net access is a tool rather than a teacher. I need to get some work done in other areas!

Since making the MLH compendium available on Internet archives, I receive queries from around the world. Nonetheless, most of the questions are discussed in previous issues, giving further impetus to wrap up this project while it's alive and well, rather than fill more issues of MLH with fluff just to keep it going. If anybody has questions about the minisport, by all means contact me. Just because I'm not sourcing more newsletters doesn't mean I don't want to talk about them any more. I'm sure my contact information will change over the next 6 months, so you'll have to be creative tracking me down. The most reliable method will probably be to contact a local Amateur Radio operator and ask them to find QSL information or a packet address for KA9SNF.

I'll continue to publish in the electronics/radio magazines. I'll be moving to Colorado in August to attend a "prestigious" Space Tactics School put on by Headquarters Space Command. After that, I'll probably be permanently moving to Colorado Springs to teach at the Air Force Academy. God willing, I'll begin training as an astronaut sometime in 1996. Selection will be this Fall.

Please provide feedback! * Internet bmork@comtch.iea.com

3023. OptoSCC card fabrication help

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-13 00:00:00 UTC
From: negaard@draagen.graceland.edu
Message-ID: <NEGAARD.95Jul13151434@draagen.graceland.edu>
Source record: 111921

Thanks to the assistance of a reader of the r.r.a. newsgroups (thanks, jesus!), I have schematics and component-placement diagrams of the OptoSCC packet-interface card for PCs, designed by Henk Z. Peek, PA0HZP. The board looks simple enough, and will certainly meet my present and projected future needs (operating packet from Linux), but...

In the archive file that jesus (EB1DIX) sent me there are no etch patterns or layouts, and the e-mail address listed in the documentation for PA0HZP appears to be dated. Therefore what I'm looking for is a source for either:

a) patterns that would allow me to etch the board myself
b) a source for the board (at a low, _low_ price, please! ;->=)
c) a layout program that would allow me to design my own from the schematics (this had probably better be free)

and...a source or complete description for the 20L10 component (I _think_ it's a PAL, or something programmable). If I'm right about what it is, I'll also need some help programming it.

This is the answer, I can feel it...if only I can get a _little_bit_ more help. ;->=

Thanks.

Hi Steve, You might want to try a roadside truckstop
that has a CB-shop. They sell all kinds of quick
disconnect mounts for CB radio's, scanner, and other
mobile/portable equipment. I would suggest NOT using
any kind of quick disconnect antenna connection, as
these inevitably fail and damage to the rig could
occcur. However, "male" and "female" slide/lockable
mounting brackets are vy common. Mounting it to your
2400 would likely require using a combination of the
standard Yaesu bracket and the male or female quick
disconnect bracket. Typically, power (13.8vdc) and
speaker (external speaker) are quick disconnected with
these mounts.73 good luck bv2/n0iat Joe in Taiwan

Hi Warren, I have modeled such a configuration and guess what? The water pipe is part of the radiator and the feed point is something like an off-center-fed gamma match unless you actually short the *top* of the pipe to the auto chassis. IMO, best thing to do is go to a bumper mounted 2 metre long antenna with a centerish hi-Q loading coil and a large tophat.

You might look into adding a ground gate jfet at the output with a 6dB
pad between the devices. The jfet gain/isolation plus the pad los should
increase your reverse by at least 16dB.

I've made a quick review of the spec's on these devices about a month ago while
looking for a VCO for a homebrew xcv'r. These look generally ok but the
Phase Noise spec left me somewhat in doubt for weak signal work. The 200-380
had only -98 or so spec @ 10khz if I remember correctly. I would like

Unless you need brand new parts, I would try a large stereo repair shop.
Older stereos had pulleys, dial cord and springs for their tuning
mechanisms. Cheap ones sometimes had the main pulley pressed onto the
capacitor, but better units used a heavy pulley with a set screw (1/4"
shaft). If you cannabilize a few, you'll probably find what you need.

Does anyone know the best method to design an amplifier to have a large reverse isolation? I've built a 82MHz amp using an MRF136. The reverse isolation is about 28dB. Does anyone know how to achieve better than this? Three possible methods that spring to my mind are:

1) Isolator - not practical at 82MHz
2) Attenuator on output - reduces gain.
3) Resonate feedback capacitance of device with an inductor. Unfortunately, this seems almost certain to make an oscillator at some frequency.

Any ideas???

>
These crystals are common. The frequency tolerance is quite
imprecise though, +-30 to +-100 parts per million, compared to 5
or 2 ppm for a communication-type crystal. Not a problem for
asynchronous communication. They are cheap and easy to get
because a huge number of identical ones are being made for the
computer market. Microprocessor crystals below 4 MHz or so cost
more, presumably because they're harder to make. About $2 to $3
is typical. Those above 4 MHz are real cheap, $0.80 or less.
That's probably why the cheap serial cards use a 18.432 MHz one
and divide it by 10, total cost for the crystal and divider is
less than for a 1.8432 MHz crystal.

BEWARE OF REPEATER JAMMER SEEKING INFO ON "FINGERPRINTING"

There's recently been a thread on rec.radio.amateur.equipment from someone claiming to be a new ham who has been mistaken for a jammer. This person reports to have been confused for the jammer by virtue of having bought a "Fingerprinted" radio off the jammer.

At different times in posts and private emails this person claimed:
To be using a girlfriends email account maryjohn@pipeline.com, but claimed not to be "Mary Johnson" whose account this appears to be.
To be Mary Johnson.
To be KB2UXI - which doesn't fit!
To be a 15 year old male.
To be a married female.
To be a male named Larry Markson.
To have no technical knowledge - desperate for help.
To have some technical knowledge and has displayed same in some emails.

I have no earthly idea if this person is legit or not. But considering the inconsistencies, caution does seem reasonable.

This is bad, bad advice ! Throughout my carreer, I was in an industry
that operates arc generating devices with power inputs of 10 to 60 MW.
Yes that's megawatts ! We measured AC current in kiloamperes ! The
unschielded output of light could do serious damage to eyes in less
than a minute. Lower powered devices might take a little longer... but
do you want to do the test on your own eyes ? The first symptom of
excessive exposure, "called arc eyes", does not appear until several
hours after exposure. Its a feeling that someone has poured a hand full
of sand in you eyes, and the rubbing only makes thing worse. Just like
a sunburn... the retina gets blisters on it. Maybe... after two days
you can recover... maybe just partly. You want to try it ? The light
level required to erase EPROMS is in the hazard range.

3037. Help solid state digital switch

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-14 00:00:00 UTC
From: ted3@ix.netcom.com
Message-ID: <3u58v3$ilr@ixnews4.ix.netcom.com>
Source record: 111846

Hello, I am trying to put together a solidstate switching device
that operates directly from a remote control airplane reciever.
I know I will have probably have to use logic devices to achive
this after looking at the signals with my scope. Here is a basic
rundown on the digital proportional control signals.

This is the servo control signal coming from the reciever and
going to the servos at minimum deflection..

This is the control signal with the controls in the neutral position.

This is the control signal with the controls in the maximum
position.

I have only ever seen one of these devices advertised.
Looking at the add I can see the following parts.

1 CD4013BE duel D flip flop
1 Optocoupler
3 Small signal transistors
1 Potiometer
1 Power switching device (SCR, Transistor) cant read the
numbers
1 capacitor
1 diode
and assorted resistors

It doesnt look like it would be hard to build one but I need somewhere to start from. If I did use a flip flop what would I use for a clock signal? I was thinking of using a non resetable monostable multivibrator to generate the clock from the existing pulses or is this even nessasary?
Is there any documentaion or better yet schematics reguarding this subject available on the net? Any assistance would be appreciated.
Please respond via email if possable.
Thanks Ted
Ted3@ix.netcom.com

You want to have a switch simply output high/low if you are
in minimum or maximum deflection only? Or do you want a digital
'level' like 0-255 depending on the deflection?

In either case, could you use an integrate and dump amplifier to
find the duty cycle of the waveform. If you want a high/low signal,
you could put this into an analog comparator. And if you want a
digital level, put it into a A/D converter.

I'm sure there's a simpler way (since the schematic you said was
relatively simple), but I don't know it.

Jake

3039. Mini-Circuits VCO's -- Good for VHF VFO's??

Newsgroup: rec.radio.amateur.homebrew
Date: 1995-07-14 00:00:00 UTC
From: cromwell@rvl2.ecn.purdue.edu
Message-ID: <3u64o1$frp@mozo.cc.purdue.edu>
Source record: 111848

I noticed an ad for Mini-Circuits' POS series VCO's. Small metal cans, they look like their DBM's. The advertised ranges are:
25- 50 MHz
38- 75 MHz
50- 100 MHz
75- 150 MHz
100- 200 MHz
150- 280 MHz
200- 380 MHz
300- 525 MHz
485- 765 MHz
685-1025 MHz
All with +7 dBm out. About US $12, at least for the half at lower frequencies.

My question is -- would one of these be suitable for something like the Rick Campbell T2/R2 phasing SSB designs? I assume you'd need a good multi-turn pot, and the pot would probably need to have good temperature stability, but could one's VCO be be as simple as that?

>
>Re DDS/PLL theory
In reply to Clark Fishman sorry I lost your details!
so I will ahve to post this
The DDS chip IS the controller also
After reading the keypad the micro goes into a softwareloop
which acts as the DDS binary adder
In Pseudocode

```
loop
add lo_byte,temp
btfsc status,carry : ? overflow
incf port_C ; Port C is the high byte
add hi_byte,port_C ; High byte of 16 bit no.
btfsc interuppt ; ?Keypress
goto loop
```

The PIC takes 4 clock cycles for most instructions
The above code takes 8 machine cycles
If at least 2 points per cycle in the output waveform
Max output frequency= 20MHz/4/8/2= 312 KHz

The output spectrum is a forest of spurs!
Hope this helps
